Glossary

Conversion mixed methods designs A type of mixed methods design in which the data of one strand of a study is the result of conversion of the data in another (for example, from qualitative to quantitative)

Design quality The degree to which all elements of investigator's research design are implemented appropriately and with fidelity

Hybrid mixed methods designs A type of mixed methods study with more than two strands/phases, utilizing more than one of the other three families of designs (parallel, sequential, conversion) in a dynamic manner

Inference (or research inference) A conclusion, understanding, or explanation derived from the results of data analysis in a research study

Inference quality The degree to which the interpretations and conclusions of a study are seen as valid, credible, acceptable, and more plausible than other possible explanations of the findings

Inference transferability The generalizability or applicability of conclusions made on the basis of the results of a study to other individuals, entities, settings, situations, time periods, or methods of data collection

Interpretive rigor The degree to which the conclusions made on in study are rooted in actual results and rule out alternative inferences based on the same findings

Mixed method research A type of research design in which the findings of qualitative and quantitative methods/approaches are integrated in order to gain a fuller understanding of the phenomenon under investigation

Parallel mixed methods designs A type of mixed methods design in which two or more strands of the study are implemented from beginning to the end relatively independently at the same time (concurrently) or with a time lag

Sequential mixed methods design A type of mixed methods design in which the questions and data of one strand comes from the completion of a previous one. For example, a qualitative strand leading to a second quantitative strand of the study

Transcendence Creating a higher-order cognitive or theoretical framework that incorporates and connects two seemingly inconstant sets of cognitions or research findings

Mixed-methods research systematically integrates quantitative and qualitative designs, data, or results of data analysis to answer complex research questions that might benefit from such a combination. One of its major strengths is that it empowers the researcher to use the most appropriate techniques for answering the research questions. Using an integrated approach has gained increasing recognition in the past three decades. Such recognition is evident in a relatively large number of books (e.g., [Bamberger, 2000](#); [Creamer, 2018](#); [Creswell and Plano Clark, 2018](#); [Hesse-Biber and Johnson, 2015](#); [Nastasi and Hitchcock, 2016](#); [Newman and Benz, 1998](#); [Plano-Clark and Ivankova, 2016](#); [Plowright, 2011](#); [Ridenour and Newman, 2008](#)). Also see *Further Reading* below), numerous articles in professional and academic journals, dissertations, conference presentations, and a dedicated journal: *Journal of Mixed Methods Research*.

[†]Deceased author.

Traditionally, quantitatively oriented researchers have worked within the postpositivist worldview and are predominantly interested in collecting numerical data with structured data-collection methods. They analyze their data using statistical techniques, and maintain a degree of objectivity in their interpretations. On the other hand, qualitatively oriented researchers emerged as a distinct reaction to what was seen, in the 1980s and 1990s as the dominant and excessive practices of quantitative research. Qualitative scholars follow a constructivist worldview and are predominantly interested in collecting narrative data using open-ended (unstructured, emergent) methods. They typically analyze their data via thematic analysis, and make holistic, value-based, and subjective inferences on the basis of the findings. Although qualitative research is often (perhaps wrongly) assumed to be exploratory, both qualitative and quantitative research may be exploratory/descriptive or explanatory/confirmatory. The dichotomizing based on this aspect of research is too simplistic to be valid (see Bergman, 2008; Tashakkori et al., 2021).

Negating the qualitative–quantitative dichotomy, mixed methods have emerged as a third alternative—allowing researchers to take relative stances on a continuum between the two. Mixed-methods researchers identify themselves as integrative and eclectic, work primarily within a pragmatic worldview (Johnson et al., 2017) to answer broad and complex research questions, collect both narrative and numerical data, employ both structured and emergent designs, analyze their data both via statistical and content analysis, and make meta-inferences as answers to their research questions by integrating the inferences gleaned from their qualitative and quantitative findings.

Mixed-methods researchers combine the characteristics of quantitative and qualitative traditions that yield answers to questions that neither approach alone can answer. This potentially enables the researchers to examine research problems from multiple perspectives and types of (qualitative and quantitative) evidence from multiple sources, leading to conclusions that may be complementary and/or confirmatory. Using an integrated approach allows one to generate new theoretical explanations or expand the current ones, as well as test these understandings in a single study, if needed.

Despite the general assumption that integrated methodology has emerged as an alternative to the strict dichotomy of the qualitative and quantitative approaches of the past century, in truth, it is well rooted in the eclectic approaches of social/behavioral science researchers of the twentieth century (see Maxwell, 2016; Peltó, 2017; Tashakkori et al., 2015; Waszack and Sines, 2003 for more details). Consistent with this inherent return-to-roots characteristic, the dominant tenet of mixed-methods research is that the research purpose and question (not the paradigm) dictates the method of inquiry.

Mixed-methods scholars do not ignore the possible impact of investigators' culture, worldview, and sociopolitical context on choosing and formulating research questions. These influences are often inherent in the purposes of the study, which, in turn, shape the research questions, and eventually lead the researcher's methods of study. Understandably, only some research purposes and questions are amenable to mixed methods. Many others might be answered more parsimoniously by utilizing either qualitative or quantitative designs/approaches, as appropriate.

Purposes and utility of mixed-methods research

Admittedly, one of the main reasons for the popularity of mixed methods is that it is more effective for answering some research questions. These are often the type of questions that are not readily answerable by either qualitative or quantitative designs/approaches, or the purposes underlying them are not reachable via qualitative or quantitative orientations, "mental models (Greene, 2007)," and techniques. At least seven reasons are often given for using such methods:

- Complementarity: Using both mixed methods for the purpose of integrating two expertly different but related answers to the research question, one gleaned from using a qualitative and the other from a quantitative approach.
- Completeness: Using mixed methods in order to obtain a fuller understanding of the phenomenon under investigation. The expectation is that such a more complete understanding will emerge if the inferences from qualitative and quantitative strands of a study are merged effectively (such an effective integration has been called "integrative efficacy" of mixed methods inferences).
- Development: Mixed methods is conducted with the explicit (preplanned or emergent) purpose of obtaining research questions, sampling framework, or data sources of a second (e.g., a qualitative) strand of the study from the first strand (e.g., quantitative).
- Expansion: Same as "developmental" discussed above, but with the purpose of expanding the answers already obtained in a previous strand of a study.
- Corroboration/Confirmation: Utilizing integrated methods in order to evaluate the credibility of inferences obtained from a (qualitative or quantitative) strand of a study. The research questions of the first strand are often exploratory, while the research questions of the second strand are often explanatory/confirmatory.
- Compensation: Utilizing mixed methods with the express purpose of compensating the weaknesses of one approach (e.g., data correction errors/biases) with the strengths of the other.
- Diversity: Conducting mixed methods with the hope/purpose of comparing and contrasting divergent pictures of the same phenomenon. (Dialectic approach in which the answers are pitted against each other; Greene, 2007).

Research questions in mixed-methods research

As we discussed earlier, the main purpose for utilizing a mixed-methods design is to answer research questions that are not effectively answerable by either a qualitative or quantitative approach alone. Such questions often have interrelated components—each following qualitative or quantitative orientations, such as questions including “what and how”, or “what and why”.

Mixed-methods questions are often seen in two non-mutually exclusive ways: (1) an over-arching question that potentially includes both qualitative and quantitative type of sub-questions, or (2) a collection of separate qualitative and quantitative type of questions, followed by a question with regard to the nature of integration (i.e., how do the answers to the two types of questions relate to each other). Both types of questions may be pre-planned, or may emerge during the course of a study, such as in emergent sequential designs discussed below (also see [Plano-Clark and Badiee, 2010](#)).

The first variation is more frequently seen in the literature. For example, one might ask: “What are the effects of teaching method X on achievement and self-perceptions of groups A and B?” Such a question might be followed by three sub-questions asking: (1) “Are groups A and B different in achievement and self-perceptions?” (2) “What are the perceptions and constructions of participants in groups A and B regarding teaching method X and its impact?” and (3) “How does teaching method X work differently in the two groups (if it indeed did)?” The sub-questions are answered in separate strands (phases) of the study. Sub-questions are components of the same question (rather than addressing related phenomena).

The second approach mentioned above includes explicitly separate qualitative- and quantitative-type of questions that are inter-related (e.g., “Does teaching method X impact the achievement and self-perceptions of students in groups A and B differently?” and “What are the perceptions of parents regarding teaching method X?”). They are followed by an explicit question about the nature of integration (for more information, also see [Tashakkori and Creswell, 2007](#)). Examples of such preplanned or emergent questions include: “do the findings of the two strands of the study agree/converge?” or “how do the two sets of answers contribute to a comprehensive understanding of the phenomenon under study?” It could be said that these later questions only address the nature/quality of integration in mixed methods studies.

Design of mixed-methods studies

Our framework for classifying mixed-methods designs is to divide them into four families that simultaneously include the sequence of procedures (parallel, sequential, conversion, hybrid) and sources of information needed to answer the research questions (s). Within each family of designs, there is variation on the basis of units of study (same/sub-sample, multiple samples, multilevel samples). There are two basic questions that the investigator has to ask and answer when making decisions about mixed methods design of their study:

“Which sequence of steps will provide a better opportunity to answer my research questions: Collecting and analyzing data sequentially (sequential mixed-methods study) or in a parallel manner (parallel mixed-methods study)?” In parallel designs, two sets of data (qualitative and quantitative) are collected and analyzed independently at the same time or with a time lag (see [Fig. 1](#)), in order to answer an overarching mixed methods research question. Despite the relative independence of multiple strands,

Fig. 1 Graphic presentation of parallel mixed-methods designs.

Fig. 2 Graphic presentation of a sequential mixed-methods design in which research questions of the second strand emerge from the findings of the first.

in these designs, investigators' knowledge of one strand (e.g., QUAL data collection or analysis) might lead to modification of another (e.g., QUAN data collection or analysis). In sequential designs, the second round of data collection and analysis is rooted in (initiated from, made possible by) the results of the first set (see Fig. 2), often in emergent manner.

An investigator might also ask "will I have an opportunity to convert my data from one type to another and reanalyze it in order to get more credible or alternative answers?" If the answer is affirmative, a conversion mixed-methods design is employed (see Fig. 3). For example, you may collect qualitative data (open-ended interviews, classroom observations, etc.), do a thematic analysis of the narrative, and make conclusions. In addition, you may also convert the obtained themes to numerical indicators that are analyzed statistically, leading to a new set of conclusions. In conversion mixed designs, the qualitative data are transformed (quantitized) into numerical indicators that may be analyzed separately using statistical techniques. Alternatively, in these studies, quantitative indicators (e.g., personality test results) might be transformed (qualitized) into qualitative data (e.g., narrative personality profiles) that are analyzed separately as if they originated from a separate sample (see Tashakkori et al., 2021 for more details). Obviously, the findings gleaned from both sets of data analysis are compared, contrasted, and integrated for better understanding of the phenomenon under study.

Fig. 3 Graphic presentation of conversion mixed-methods designs with multiple questions—one type of data that are also transformed and reanalyzed.

In practice, many mixed-methods studies use a combination of these three families in an iterative and dynamic manner, as needed. These studies have been labeled hybrid mixed methods studies (or, what in the past, was called fully integrated mixed-methods designs, [Teddle and Tashakkori, 2009](#)). This is the ideal design in mixed-methods studies because it allows the researcher to dynamically utilize qualitative and quantitative approaches in whatever combination/sequence needed, and use the insights from one type of data/process to modify/enhance the other within and across stages of the study. Hybrid mixed designs employ combinations of the other three families, with more than two strands.

In addition to the decisions about the sequence of strands and the possibility of data conversion, a mixed methods researcher must also make decisions about possible sources of data in order to find the best answers to the overarching research question. All qualitative and quantitative data might be obtained in the same sample. Alternatively, one type of data might be collected in a sub-sample of the other. This type of sampling (same, or sub-sample) leads to both type of data being available about some or all individuals in the study. Obviously, possibility of contamination (one data collection method creating reactivity in the sample) might be a disadvantage of this type of sampling (for example, focus groups following a survey study). Alternatively, qualitative and quantitative data may be collected in independent samples (i.e., two separate sub-samples). Obviously, in this type of sampling it is not possible to compare the qualitative and quantitative data/findings at the individual level. On the other hand, the possibility of either type of data collection impacting (i.e., contaminating) the other is also not present, potentially leading to more credible answers to the overarching research question.

Data-collection strategies in mixed-methods research

During the course of a mixed-methods study, an investigator collects a variety of narrative and numeric data, using a combination of qualitative (open-ended, naturalistic, and holistic) and quantitative (close-ended, structured, and variable-specific) approaches. It is possible to collect both qualitative and quantitative data in a single data-collection strategy. For example, in a mixed-methods study, observations may be recorded by taking extensive notes to record as many of the interactions as possible, while also using highly structured protocols yielding numerical data. Most observations include a combination of both unstructured (open-ended) recording and structured (closed-ended) items to record the behaviors/events. Similarly, interviews and questionnaires may be used to collect both types of data in a mixed-methods study. Open-ended interviews or questionnaires provide qualitative data, while structured (closed-ended) interviews and questionnaires provide quantitative data. Once again, most questionnaires and interviews in research do some of each. It should be noted that these mixed data are common in many studies that are not readily identified as mixed, such as in experiments, surveys, ethnographies, and case studies, but are not always analyzed fully (i.e., via both statistical and thematic analysis) that lead to pertinent inferences based on the results.

In mixed-methods studies, interviewers conduct funnel-sequenced interviews ([Teddle and Tashakkori, 2009](#)) that start from general questions/topics ("tell me about your school") and are gradually focused on more specific emerging or preplanned issues ("how do you like your math class?"). These interviews are conducted individually or in focus groups. Focus groups combine interviews, discussions, and observations of group interactions by the researcher(s), and, often, provide mixed data. Mixed questionnaires provide two types of data as well, although they are less dynamic (interactive) than interviews. Computerized questionnaires provide a greater potential for using both format.

In addition to using one method of data collection for obtaining both qualitative and quantitative data, mixed data might be obtained through multiple modes of data collection that each provide either qualitative or quantitative data (e.g., close-ended questionnaires among students and unstructured observations of teachers).

Data-analysis strategies in mixed-methods research

Highly consistent with the type of design, in mixed methods the narrative and numeric data may be analyzed relatively independently, or in an interdependent sequential manner. A detailed discussion of these analyses is beyond the scope of this article. Hence, we refer you to other sources (e.g., [Bazeley, 2018](#); [Creswell and Plano Clark, 2018](#); [Tashakkori et al., 2021](#)).

An example of data analysis in parallel mixed designs is when the investigator statistically compares an experimental and control group in a Randomized Control Trial (RCT) while also conducting a thematic analysis of post-experimental interviews (or open observation notes, if the individuals/groups were observed). An example for data analysis in sequential designs might be the formation of groups of people/settings on the basis of qualitative data-analysis results, and then comparing these groups statistically (analysis of variance, discriminant function analysis, etc.), using the available (or newly collected) quantitative data.

Integrated inferences in mixed-methods studies

As mentioned above, integration of the findings and conclusions are the primary objective of mixed methods studies (see [Plano-Clark, 2019](#)). Although a degree of agreement/consistency between the findings of qualitative and quantitative strands of a mixed-methods study might be desirable (leading to greater certainty about the conclusions), such consistency is not required. Integration in mixed methods denotes elaboration, complementarity, completeness, confirm/disconfirmation, and so forth. Lack of consistency

is examined carefully by mixed-methods researchers, to see if it might be a result of possible problems in data collection and analysis or the conclusions derived from the results. If such an examination does not reveal problems in the design, results, or interpretations, lack of agreement might indicate that the two sets of answers to the research question exist: The results reveal two different aspects of the same phenomenon, one set might provide the conditions for the applicability of the other, or there is a possibility that there are two plausible, but different, answers to the question (see [Erzberger and Kelle, 2003](#)). Lack of consistency (disagreement, discordance) might lead to *transcendence*, the creation of a new higher order theoretical explanation for the phenomenon or behavior.

Mixed methodologists have discussed the importance of developing quality criteria and audits that incorporate and expand the qualitative and quantitative concepts. For example, [Tashakkori and Teddlie \(1998\)](#) (see the section titled “Further reading”) have proposed using the term *inference quality* as a term to incorporate the term internal validity used by quantitative researchers and credibility used by qualitative researchers. Employing such an umbrella term gives mixed-methods researchers the opportunity to incorporate elements of quality assessment and strategies to deal with possible problems in making inferences (e.g., threats to quality) into a single integrative framework.

In such an integrative framework, qualitative concepts—such as prolonged engagement, peer debriefing, triangulation, audit trail, negative case analysis, and others—can be used to enhance the quality of inferences gleaned from quantitative findings. Similarly, concepts such as consistency between elements of the design, design quality, construct validity, investigator expectancy effects, and participant reactivity may be used as safeguards when making inferences on the basis of qualitative findings. In other words, using such an umbrella framework sensitizes the researcher to multiple perspectives when considering the quality/validity of their interpretations. A similar logic is applicable to evaluating and enhancing the quality of data that the findings and inferences are based on (i.e., data quality).

Within this integrative framework, conclusions that are made on the basis of the results of data analysis are evaluated in terms of (1) inference quality and, (2) inference transferability. We will discuss transferability (i.e., generalizability, external validity, transferability in QUAL research) below. Quality of inferences/conclusions are dependent on (a) quality of the research design that leads to the results of data analysis (i.e., “Design Quality”), and (b) quality of the conclusions that are made on the basis of such results (i.e., “Interpretive Rigor”).

Design quality is the degree to which: (I) the process of data collection and analysis is appropriate for answering the research question set forth (Design Suitability), (II) the process is implemented with fidelity (Implementation Fidelity), (III) the data are collected and analyzed appropriately (Analysis Adequacy), and (IV) all the design components are consistent with each other (Within-Design Consistency).

Interpretive rigor addresses the effectiveness of making interpretations and conclusions on the basis of the obtained results. At its basic form, it might be conceptualized as the degree to which alternative plausible explanations for the obtained results can be discounted or ruled out. Such rigor depends on meeting a number of criteria: (I) the degree to which the conclusions are consistent with the findings that they are based on (Interpretive Consistency), (II) there is agreement between interpreters such as peers, scientific community and/or the participants in the study (Interpretive Agreement), (III) the interpretations are consistent with the state of knowledge about the phenomenon (Theoretical Consistency), (IV) and each inference is distinctly more credible than other possible interpretations of the same results (Interpretive Distinctiveness). These standards might be applicable to any research project (QUAL or QUAN) or strand of a mixed methods study. Two other aspects of interpretive rigor are only applicable to mixed and multiple methods research: (e) the degree to which the results and inferences gleaned from multiple strands of the study are integrated as answers to the overarching question (Integrative Efficacy) and (f) the degree to which such final answers are effective answers to the umbrella integrated (mixed) research question (s) and purposes set forth (Interpretive Correspondence).

Please see [Tashakkori et al. \(2021\)](#) for details with regard to the components of these two quality criteria.

Transferability of inferences in mixed-methods studies

Inference transferability incorporates the qualitative concept of transferability and quantitative concept of generalizability or external validity. It is broadly defined as the degree of applicability or generalizability of conclusions of a study to other individuals or entities (population transferability), other settings or situations (ecological transferability), other time periods (temporal transferability), or other methods of observation/measurement (operational transferability).

We have differentiated the transferability of conclusions from the criteria about quality/rigor of such conclusion because any conclusion in a study might be transferable to a degree to similar other setting and people. The degree of transferability is dependent on the similarity of the “sending” and “receiving contexts.” Although the researcher tries to maximize the degree of transferability of the conclusions made in the study, the ultimate evaluator of that degree is the consumer of research. Providing in-depth details of the study assists such a consumer in making judgments about the degree of transferability.

Conclusions

Mixed methods research is arguably closer to our daily problem-solving efforts than the two approaches (QUAL, QUAN) that it attempts to integrate ([Tashakkori and Teddlie, 2010](#)). Mixed methodology puts each component of a research project (purposes,

questions, data, data analysis, design, inferences, etc.) on a continuum between alternative qualitative and quantitative approaches/conceptualizations. Mixed-methods research is often based on the premise that the research purpose/question—not the paradigm—dictates the method of inquiry.

An advantage of mixed-methods is that it encourages researchers to think in terms of multiple continua rather than a single categorical dichotomy of qualitative and quantitative approaches, employ multiple perspectives as needed, use multiple methods that are rooted in qualitative and quantitative traditions, and interpret the findings freely without the imposed constraints of either of the two broad approaches to research.

A challenge for the mixed-method researchers is that they must learn specific data collection, analysis, and interpretation techniques that have been traditionally identified as being qualitative or quantitative. They must also learn how to integrate understandings gleaned from these complementary or competing methods in order to reach meta-inferences that better inform other professionals and stakeholders. There is an underlying assumption that the more perspectives one can get of a particular situation, the more complete the understandings are likely to be (i.e., a gestalt, or whole insight, that is bigger than the sum of its component parts). The value of mixed methods to researchers may not solely be in empowering them to use all possible tools for answering their research question, but also in becoming better informed as a result of integrating the findings of these methods.

Perhaps one of the challenges facing mixed methods is linked to its aging. As a research approach with a community of scholars expanding in at least three decades, mixed methods is reaching a mature stage. Nevertheless, it is still struggling with basic issues of conceptualization/definition. It is not clear if mixed methods denotes research projects (a) that utilize two types of design (e.g., experimental and case study) to answer a research question, (b) include two type of data that are collected/converted and/or analyzed separately (e.g., numeric and narrative data), or (c) are mixed in methods of data analysis and inferences based on the results. The least controversial, perhaps, is conceptualizing mixed methods in terms of two or more types of designs/methodologies, at least one with qualitative approach/perspective (e.g., ex-post-facto, survey, quasi-experiment) and the other from qualitative (e.g., ethnography, case study, phenomenology). Conceptualizing mixed methods in terms of two types of data is the most common and also perhaps the most controversial. For example, is an experiment with open and structured (e.g., a “funnel-sequenced”) interview leading to two types of data that are analyzed accordingly a mixed design? (or perhaps, should it be called a mixed experimental design?) Similarly, should ethnographic studies with both types of data be called mixed? (e.g., see [Pelto, 2017](#) for examples). Unfortunately, definitions of mixed methods in the literature (especially those defining in terms of “data”) are fraught with ambiguity from this point of view, and need further consensus.

Another interesting dilemma facing the mixed method community goes back to its roots. Mixed methods emerged in 1980s as a third community negating the dichotomy of QUAL and QUAN approaches. In doing so, it was initially an attempt to bring the other two communities together, providing an umbrella. However, it is in danger of becoming a distinct category itself, expanding the dichotomy into a trichotomy of disparate communities. This may be seen in textbooks in research methodology, with distinct walls between sections that are devoted to QUAL, QUAN, and mixed methods, rather than teaching research as mixed (conceptualized in terms of a combination of QUAL and QUAN-types of designs). There are few exceptions to this trend in the textbooks that discuss independent research designs (ethnography, ex-post-facto, experiment, case study, etc.), each capable of collecting and analyzing numeric and narrative data in pre-planned or emergent ways. An alternative way to think about mixed methods is to conceptualize it in terms of continuity between many components of ANY research project (please see multi-dimensional view of mixed methods in [Tashakkori et al., 2021](#), p. 44). Such a conceptualization assumes that most research projects are mixed in some form and to some degree in one or more of their components (worldview, purpose, question, data, data collection methods, data analysis techniques, inference), each anchored in both (QUAL and QUAN) traditions/approaches.

Introduction

Early in the formalization of mixed methods research as a field, Teddlie and Tashakkori (2003) identified that the “paradigmatic foundations” of mixed methods research was a key issue for the field. Nearly 2 decades later, this topic is still discussed (cf. Coates, 2020). Identifying one’s philosophical underpinnings is an important part of making the mixed methods research process more credible, transparent, and trustworthy (Howes, 2017). This discussion provides a justification for the decisions made during this process (Harrits, 2011; Howes, 2017). Articulating a clear philosophical paradigm can make one’s stance and research more accessible to audiences across disciplinary, national, and language boundaries (Fetters and Molina-Azorin, 2019).

The purpose of this chapter is to introduce the philosophical underpinnings of mixed methods research in educational research. First, I provide a definition for philosophical paradigm along with how it differs from other frameworks such as a methodological paradigm (e.g., qualitative research), theoretical framework, or conceptual framework. Next, I outline the four main elements to a philosophical paradigm: ontology, epistemology, axiology, and methodology. After defining mixed methods research, I then discuss several philosophical paradigms that are used in mixed methods research, describing each of the four elements within that paradigm and highlighting published examples of mixed methods research in education using that philosophy. The paradigms I describe in detail are positivism, postpositivism, critical realism, constructivism, pragmatism, transformative-emancipation, postmodernism, and dialectical pluralism. I also describe two meta-paradigms, yinyang philosophy and Indigenous philosophies, based on emerging research in mixed methods about these frameworks.

Philosophical paradigm

A *paradigm* refers to a community’s set of shared beliefs, values, and practices (Shannon-Baker, 2016). A *philosophical paradigm* refers to a set of beliefs, values, and practices about the nature of reality, how knowledge can be generated, and who generates it about that reality (Plano Clark and Ivankova, 2016; Shannon-Baker, 2016). Researchers’ philosophical paradigms are influenced by their education and training, discipline, and sociohistorical contexts (Creswell and Poth, 2018). Other researchers have referred to philosophical paradigms as *philosophical stances* (Greene, 2006; Greene and Hall, 2010; Maxwell and Mittapalli, 2010), *philosophical assumptions* (Plano Clark and Ivankova, 2016), or part of a *mental model* including philosophical assumptions and predispositions to particular methodological approaches (Greene, 2007).

A philosophical paradigm might be connected to but is different from a *methodological paradigm*, which indicates a set of values, practices, and expectations for rigor and quality that directly impact one's research methods. For example, qualitative research and quantitative research have been referred to as paradigms (e.g., Collins et al., 2006; Cooper and Hall, 2016; Corr et al., 2020). The *paradigm wars* reflect the conflict between researchers entrenched in philosophical and/or methodological paradigms and affiliated worldviews (Alise and Teddlie, 2010; Ponce et al., 2020; Shannon-Baker, 2016). Similarly, a philosophical paradigm differs from a *theoretical framework*, which identifies a set of assumptions about a particular topic or phenomenon (Plano Clark and Ivankova, 2016), and a *conceptual framework*, which defines key constructs related to a research study and how those constructs have been studied in the past.

A philosophical paradigm and research methodology might be aligned but these are neither inseparable nor synonymous. Certain research practices might align with a specific methodology and philosophical paradigm (e.g., strict structured observation of the frequency of events → quantitative research → postpositivism) whereas other methods or methodologies might align with multiple frameworks. Researchers can intentionally choose to combine, mix, or otherwise integrate multiple elements from several philosophical paradigms, referred to as using a *multiparadigmatic approach*, or use specific paradigmatic frames for a given research problem or setting (Greene, 2007; Reichardt and Cook, 1979; Shannon-Baker, 2016). Some scholars argue that philosophical paradigms are incommensurable with one another (Lincoln and Guba, 2011) whereas others critique this purist approach (Greene, 2007; Tashakkori et al., 2021). Additionally, others present these paradigms as more on a spectrum rather than strict, exclusionary and static categories (Hammersley, 1992; Shannon-Baker, 2016) where in some cases, a single paradigm could have multiple offshoots such as how there are multiple forms of pragmatism (Johnson et al., 2017).

Some researchers argue that they can conduct studies without influence from or specific attention to their philosophical paradigms, referred to as an *aparadigmatic* stance (Greene, 2007; Tashakkori et al., 2021). For example, this stance might be used (consciously or unconsciously) in relatively small and applied research studies where evaluating a specific context is seen as more important than attending to seemingly abstract philosophical notions (Greene, 2007; Tashakkori et al., 2021). However, some researchers have argued that philosophical assumptions, beliefs, and practices cannot be separated from one's research process (Shannon-Baker, 2016).

Educational researchers, when they explicitly identify their philosophical paradigm, may indicate this underpinning in a frameworks section (where theoretical and conceptual frameworks may also be described), in a methods section, and/or in a section about the researcher's *positionality*, which is where the researcher names their specific contexts, personal experiences, identities, personal and professional beliefs, predispositions, their role in the research process, and other aspects that might have influenced the study (Berger, 2015; Creswell and Poth, 2018). This positionality statement is an important place for researchers to demonstrate their critical reflexivity about their role and influence in a research study (Berger, 2015).

Elements of a philosophical paradigm

A philosophical research paradigm includes ontological, epistemological, axiological, and methodological components that are distinct but interrelated that then influence one's research methods and practices (see Fig. 1). Although these components might appear to be linear in influence, they are interrelated, depicted using dashed lines between each component and cyclical facing arrows.

Fig. 1 The relationships between ontology, epistemology, axiology, and methodology, and their influence on research methods and practices within a given research philosophy.

Ontology

Ontology refers to one's beliefs, understandings, and assumptions about the nature of reality (Mason, 2002; Tashakkori et al., 2021). A key ontological question is "What is the form and nature of the social world" (Waring, 2017, p. 16). Considering one's ontology in the research entails asking what groups of people, institutions, and social processes are connected to the study (Mason, 2002). Ontology influences the research process through one's methods and how findings are represented (Alerby, 2000). For example, a researcher who believes that reality is complex and depends on an individual's perception would use methods that emphasize individual interpretations of their experiences (Alerby, 2000). Alerby (2000), for example, included a wide representation of children during sampling knowing that their individual experiences of their realities as children differs among them. Additionally, a philosophical paradigm that emphasizes multiple realities and how individuals construct their own perceptions of reality would emphasize representing findings from those multiple perspectives (Creswell and Poth, 2018).

Epistemology

What one understands about reality (ontology) influences our understandings about epistemology (Howes, 2017). *Epistemology* refers to how a person or group creates, obtains, and measures knowledge as well as the relationship between an individual/group and knowledge (Mason, 2002; Tashakkori et al., 2021). Epistemology identifies what is considered "knowledge" and what is considered "evidence" of knowledge (Creswell and Poth, 2018). A key epistemological question is "How can what is assumed to exist be known" (Waring, 2017, p. 16). One's epistemology also influences the research process. For example, epistemology influences how one frames research questions and hypotheses; if one's epistemology states that personal reflections about an experience are valid sources of knowledge, they can frame research questions based on those reflections (Creswell and Poth, 2018). Critiques from reviewers about whether a sample size is large enough or if quotes from participants provide rich details are critiques about evidence and therefore critiques indicating the reviewers' epistemological beliefs about evidence. In another example, Garcia and Mayorga (2018) described how Eurocentric and white epistemologies have heavily influenced the use of quantitative approaches as the only valid source of evidence about a phenomenon. They instead position their epistemologies as Chicana feminist and Latino scholars respectively as important foundations for their critique of how race and ethnicity has been measured in The Freshmen Survey used in higher education research. One's epistemology influences how one frames research questions and hypotheses, what data is collected and how, how it is analyzed, and how the methods and findings are represented.

Axiology

The axiology element of a philosophical paradigm blends how one understands reality (ontology) and how one creates and measures knowledge (epistemology). *Axiology* refers to the specific values one has about research, knowledge, and research methods and practices and the influence those values play in the research process (Tashakkori et al., 2021). Axiology recognizes that researchers make value-based judgments about research methods and ethics (Lincoln and Guba, 2011; Sandelowski, 2003). Researchers who are more aware of their philosophical paradigms can intentionally use their paradigms to enhance the authenticity of their work (Hesse-Biber, 2010; Lincoln et al., 2011).

Despite how some researchers overlook axiology (Hesse-Biber, 2010; Mertens et al., 2010), this element of philosophical paradigms influences much of the research process. For example, studies being conducted with humans and non-human animals need to account for research ethics in seeking institutional review board approval for their study (Biddle and Schafft, 2015). Axiology informs a researcher about which research questions are worth asking (Creswell and Poth, 2018). Camacho (2020), who studied academic migrants' experiences with advocating for better working conditions, emphasized the axiological importance of engaging in emancipatory research practices such as asking how one's data analysis procedures help to advance social justice initiatives when working with marginalized communities. The selection of specific quotes to represent one's themes represents value-based judgments about which quotes serve as good evidence (Denzin, 1989). Even whether to include a discussion of one's values and positionality in a study is influenced by their axiology, or their value for such discussions, as well as whether these contexts are seen as influencing the study.

Methodology

A research *methodology* refers to an overarching frame that guides values, practices, and decisions about research methods whereas *research methods* are the specific practices and procedures used in a study (Howes, 2017). A key question for one's methodology is "What procedure or logic should be followed" (Waring, 2017, p. 16) in the study. A key question for one's methods is "What techniques of data collect [and analysis] should be used" (Waring, 2017, p. 16). Research methods relate directly to one's research purpose and questions. Methodology is separate but related to one's philosophical paradigm. A given paradigm does not in most cases assume or align with a single research methodology; many philosophical paradigms align with multiple research methodologies and research methods.

Researchers can use their philosophical paradigm to evaluate the quality of their methods and interpretations (Howes, 2017). The process for engaging in one's philosophical paradigm has been presented as linear, using one's perspectives and philosophical assumptions to guide the research design process (e.g., Creswell and Poth, 2018), as well as ongoing and recursive (Howes, 2017). Howes (2017) for example traced how four domains of methodology impacted and connected to her work: philosophical paradigms, inquiry logics that inform the methodology, specific considerations that guide the methods used, and sociopolitical commitments to the context, researcher's own values, and research ethics.

Framing mixed methods research and philosophical paradigms

Mixed methods research is a research methodology that intentionally mixes, combines, and/or integrates more than one methodological approach in a single study (Shannon-Baker, 2016). Some mixed methods scholars argue that this mixing can also occur at the philosophical level (e.g., Corr et al., 2020; Greene, 2007). Mixed methods research has been widely applied in educational research worldwide (cf. Shannon-Baker, 2022).

Mixed methods research takes place within a socioecological framework where the researcher's own philosophical paradigm(s) are part of their personal contexts; these contexts influence the mixed methods research process (Plano Clark and Ivankova, 2016). These contexts can provide a kind of "feedback loop" to the mixed methods research process (Tashakkori et al., 2021, p. 23). Specific to education, the contexts that influence a mixed methods research study include but are not limited to: national curriculum; national or other standardized assessments; evaluation measures of schools, administrators, teachers, and students; teacher and leadership training requirements; shifting to online mediums in the wake of the COVID-19 pandemic and natural disasters; the form and function of schooling at the primary, secondary, postsecondary, and postgraduate levels; etc.

Mixed methods researchers can intentionally operationalize a philosophical paradigm that aligns with their planned research design (Creswell and Plano Clark, 2017). Understanding the differences and interconnections between one's philosophical paradigm and their research process is an important element of mixed methods research. Stakeholders may have different philosophical assumptions which impact their beliefs, values, and preferences for particular types of methods and data. As a result, mixed methods researchers can connect to these differences through the use of culturally appropriate methods and representations for specific stakeholders (cf. Shannon-Baker and Martinez, 2022). This is an important affordance to using mixed methods research: being able to speak to different stakeholders across diverse worldviews (Hesse-Biber, 2010).

Philosophical paradigms in mixed methods research in education

Mixed methods research has been conducted in relationship to many different philosophical paradigms, which is common for young research fields and approaches (Tashakkori et al., 2021). There are several philosophical paradigms that mixed methods researchers operationalize in educational research. These include positivism, postpositivism, critical realism, constructivism, pragmatism, postmodernism, and transformative-emancipation. Each has its own ontological, epistemological, and axiological beliefs that influence the methodological approaches used within that paradigm though many of these paradigms overlap with one another (see Fig. 2). Other philosophical paradigms, such as dialectical pluralism, yinyang philosophy, and various Indigenous philosophies, are based on beliefs that not only overlap with other philosophies but also describe the relationship between these frames.

Other publications additionally offer helpful comparisons of some of these philosophies (e.g., Plano Clark and Ivankova, 2016; Shannon-Baker, 2016; Tashakkori et al., 2021). It is important to note that although each paradigm is described separately below, there is overlap in the ontological, epistemological, axiological, and methodological features, which is why Fig. 2 portrays their comparisons as a spectrum rather than distinct, static categories. I represented dialectical pluralism, yinyang philosophy, and Indigenous philosophies as metaparadigms, forming a dotted box around the other philosophies, for how these paradigms describe relationships between paradigms; ontological, epistemological, and axiological beliefs; and methodological practices.

Positivism and postpositivism

Positivism is a philosophical paradigm that is centered on the ontological belief that reality is measurable and encompasses only what one can directly observe (Lincoln and Guba, 1985; Tashakkori et al., 2021). Axiologically, positivists tend to believe that research can and should be without value judgments, thereby emphasizing researcher objectivity (Tashakkori et al., 2021). This value centers the researcher as the one with power in the study (as opposed to the participants or others) (Hesse-Biber, 2017). The role of research in this paradigm is to observe and measure patterns in reality to test hypotheses or make predictions about reality using deductive reasoning and quantitative methods (Hesse-Biber, 2017; Tashakkori et al., 2021). They also use other methods that emphasize researcher objectivity through standardization of research practices, data collection, and analysis (Hesse-Biber, 2017).

Postpositivism is a more recently developed philosophical paradigm that is largely based in positivism but recognizes the impact of an individual's experiences and values on their perceptions of reality and therefore the research process (Plano Clark and Ivankova, 2016). Ontologically, postpositivists assume that there is a single reality that can be approximated by removing the researcher's influence on a study and creating more standardized research methods (Tashakkori et al., 2021). Postpositivism

Fig. 2 A spectrum of ontological, epistemological, axiological, and methodological features of different philosophical paradigms.

emphasizes researcher objectivity and independence from the research process and participants. Researchers who hold this philosophical paradigm often seek out methods that remove them from the process, such as full observation and bracketing. This paradigm is often associated with quantitative research (Phillips and Burbules, 2000), but may also be applied in qualitative research (Creswell and Poth, 2018; Hesse-Biber, 2017). Mixed methods researchers with this paradigm “often prioritize the quantitative methods, ‘quantitize’ qualitative findings for statistical analysis, and emphasize causal inferences and generalizations” (Plano Clark and Ivankova, 2016, p. 198). For example, De Lisle (2013) combined critical realism with postpositivism to frame his evaluation of the continuous assessment programs in Trinidad and Tobago. These assessment programs are used to provide summative and formative assessments, policies, and procedures for in-school teachers. Postpositivism in particular was used to inform the quantitative phase of the evaluation.

Critical realism

Critical realism is aligned closely with the ontological beliefs of postpositivism that reality can be approximated (Guba, 1990; Maxwell and Mittapalli, 2010; Tashakkori et al., 2021). Critical realists’ ontology is based on the belief that reality includes what one perceives as well as “mental phenomena” (Plano Clark and Ivankova, 2016, p. 201). This ontology recognizes the influence of contexts thereby limiting complete objectivity (Shannon-Baker, 2016). Therefore, epistemologically, critical realists argue that we should study peoples’ interpretations of the world in order to understand their experiences (Danermark et al., 2002). Although some describe critical realism based more on its ontological differences with other frameworks (e.g., Tashakkori et al., 2021), some educational researchers and mixed methods scholars alike have adopted this paradigm in their work.

Mixed methods researchers use this stance to explore divergent findings across data sets or when compared to relevant literature, and recognize that a researcher’s values and ethics influence the research process (Plano Clark and Ivankova, 2016; Shannon-Baker, 2016). Critical realists emphasize the impact of contexts in the mixed methods research process, thereby aiming to include a wide representation of voices as well as accounting for the influence of contexts during interpretation (Plano Clark and Ivankova, 2016). In addition to De Lisle (2013) who combined critical realism with postpositivism, another example of applying a critical realist approach in mixed methods educational research comes from Ubha and Cahill (2014) who studied primary school children’s relationships with classmates, teachers, and other adults in the UK. They took a “critical realist position in order to use a ‘triangulation’ strategy” to bring together their various data sets including questionnaires, quantitative scales, and interviews (p. 278). In their case, it was critical realism that necessitated bringing together multiple data sets to examine children’s relationships.

Constructivism

Constructivism is a philosophical paradigm that ontologically emphasizes how an individual actively constructs their own notions of reality through their cognition (Lincoln and Guba, 1985; Schwandt, 1997) resulting in the existence of multiple realities. A researcher who believes in this paradigm emphasizes participants' own constructions, descriptions, and narrations of their lived experiences as well as the belief that knowledge is co-constructed between researcher and participant (Tashakkori et al., 2021). These researchers also recognize that they cannot be separated from the research process and instead see this as a positive influence on the research (Lincoln and Guba, 1985; Tashakkori et al., 2021). Some scholars who use constructivism have argued it is incompatible with other paradigms (e.g., Lincoln and Guba, 1985). However, this paradigm not only connects to other paradigms often used in mixed methods research (such as pragmatism and transformative-emancipation) but is also used on its own.

Methodologically, constructivism is often associated with qualitative research (Plano Clark and Ivankova, 2016; Tashakkori et al., 2021). Constructivist researchers emphasize inductive research methods (Tashakkori et al., 2021). Mixed methods researchers from this paradigm "often prioritize the qualitative methods, limit the research to a small number of information-rich cases, and emphasize each researcher's reflexivity and interpretations" (Plano Clark and Ivankova, 2016, p. 199). For example, Strayhorn (2015) studied the Black men students' readiness and preparation for a career in a science, technology, engineering, or mathematics field at Historically Black Colleges and Universities and predominantly white institutions in the USA. He used online surveys followed by individual interviews with students. Strayhorn identified that this study came from "an epistemological approach anchored in [a] pragmatic, constructivist tradition" (p. 50) that recognized the contextual influencing factors in these men's experiences. He stated that he used a constructivist approach because it aligned with his own ontology, epistemology, and his "own commitments to social justice" (p. 50). In another example, Smeda et al. (2014) applied constructivist learning principles, which emphasize students' active engagement in the construction of their own knowledge, in their multi-site case study in Australia on the impact of digital storytelling on students' engagement and learning. Teachers in the study were trained on digital storytelling, which centers the storyteller sharing their own experiences through digital media. Their use of digital storytelling in their teaching was then evaluated using a quantitative rubric, interviews, and observations. Smeda et al. found that using digital storytelling supported constructivist approaches to learning.

Pragmatism

At its core, *pragmatism* is a philosophical paradigm that aims to identify practical solutions to real world problems (Tashakkori et al., 2021). Pragmatic beliefs range on the spectrum between constructivism, critical realism, and postpositivism. Similar to constructivists, pragmatists ontologically contend that perspectives about reality are wide-ranging and situated in current understandings and experiences (Johnson and Onwuegbuzie, 2004; Plano Clark and Ivankova, 2016; Strayhorn, 2015). Epistemologically, they contend that researchers gain knowledge through a combination of independent observations and subjective interpretations with the aim of investigating the consequences or influence of one's understandings of reality (Johnson and Onwuegbuzie, 2004; Morgan, 2007; Plano Clark and Ivankova, 2016). Axiologically, pragmatists value the influence of subjectivities in the research process, but otherwise methodologically choose whether to embrace this influence or mitigate it (Johnson and Onwuegbuzie, 2004; Plano Clark and Ivankova, 2016). Methodologically, pragmatists' decisions in the research process are guided by the central goal of wanting to identify changes to address social problems and thus use any methods that best address the research purpose and questions (Tashakkori et al., 2021).

Johnson et al. (2017) demonstrated how classical pragmatists such as John Dewey and others align with particular equal, quantitative, or qualitative priority mixed methods designs.

Classical pragmatism aimed to find a "middle ground" between those who recognized the influence of philosophical paradigms and those who were skeptical of the influence (Johnson and Onwuegbuzie, 2004, p. 18). This belief persists in pragmatists' rejection of the incommensurability of qualitative and quantitative methods; pragmatic mixed methods researchers instead believe in the complementarity of these approaches (Tashakkori et al., 2021). For example, in their investigation of the impact of a four-week study abroad program in China for teachers' intercultural competence, He et al. (2017) applied pragmatism in rationalizing why mixed methods research was necessary. They argued that this paradigm was their foundation for selecting multiple methods "to corroborate and elaborate" on one another (p. 150). Strayhorn (2015) similarly applied pragmatism in his mixed methods educational research study. Pragmatism is often presented as a primary philosophical paradigm for mixed methods research (Johnson et al., 2007; Johnson and Onwuegbuzie, 2004; Tashakkori et al., 2021) because it "offers an epistemological justification [...] for mixing approaches and methods" (Johnson et al., 2007, p. 125). However, as this chapter demonstrates, mixed methods educational researchers apply many different philosophical paradigms in their work.

Transformative(-emancipation)

Transformative-emancipation is a philosophical paradigm that ultimately aims to use research to bring about positive social change to address injustices and inequity (Mertens, 2003, 2007). Although commonly referred to as the *transformative* paradigm, Mertens (2003) originally referred to this paradigm as "the transformative-emancipatory paradigm" (p. 135). Use of the full phrase (transformative-emancipation or transformative-emancipatory) keeps the focus of this paradigm directly on disrupting systems of oppression for the purpose of liberation from those systems (Shannon-Baker, 2016). Transformative-emancipatory researchers view reality as

subjective and socio-historically situated (Tashakkori et al., 2021). Multiple realities are influenced by social structures, especially those structures that perpetuate oppression and power differentials (Mertens, 2003; Plano Clark and Ivankova, 2016). As a result, researchers use their own values and subjectivities to meaningfully influence the research process (Plano Clark and Ivankova, 2016) as well as collaborators' perspectives and values. In this way, "objectivity is valued [for] providing a balanced and complete view" of an experience (Mertens, 2003, p. 141). Epistemologically, transformative-emancipatory researchers view knowledge creation as a process that takes place through collaboration with others (Plano Clark and Ivankova, 2016). Axiologically, this paradigm centers the lived experiences of marginalized communities and the use of research to bring about change to address social inequities (Mertens, 2003, 2007).

Transformative-emancipatory researchers emphasize working in collaboration with others throughout the research process by including research participants and other stakeholders in the research decision making (Mertens, 2003; Plano Clark and Ivankova, 2016; Tashakkori et al., 2021). For example, Garnett et al. (2019) combined transformative-emancipation with mixed methods and youth participatory research to explore the implementation of restorative practices in a school district in the USA. They found that this combination of methods with a transformative approach allowed researchers "to flatten hierarchies and actively engage marginalized youth to address the structural and programmatic inequities they experience in school" (p. 305). Mertens (2007) argued that combining mixed methods with a transformative-emancipatory approach is necessary to address the cultural complexities of social inequities. In another example, Garcia and Mayorga (2018) combined this paradigm with Critical Race Theory to examine how race and ethnicity are constructed in The Freshman Survey used in the USA to track access to higher education. Combining this paradigm and theoretical framework prompted them to ask critical questions about how race and ethnicity constructed through how questionnaires are framed, how data are disaggregated versus aggregated, and how samples are constructed in mixed methods educational research.

Postmodernism

The philosophical paradigm of *postmodernism* positions all knowledge and perspectives as equal and influenced by systems of power, but otherwise unstructured (Hesse-Biber and Kelly, 2010; Plano Clark and Ivankova, 2016). As a result, postmodernists reject the notion of objectivity in favor of socially situated and contextualized forms of knowledge (Hesse-Biber and Kelly, 2010). Similar to constructivism, postmodernists consider their own values and beliefs as an important influence on the research process but are no more important than participants' views or other stakeholders in the research process (Hesse-Biber and Kelly, 2010). Methodologically, postmodernist researchers often aim to expose and deconstruct systems of power through their research (Hutcheon, 1988; Plano Clark and Ivankova, 2016). Unlike other philosophical paradigms that might aim for social change, postmodernists do not aim to replace current systems of hierarchy (Rosenau, 1992). Instead, they aim to deconstruct texts, which can be policies, practices, institutions, or other systems, for their inherent power structures (Derrida, 1976; Hutcheon, 1988). This process of deconstruction involves a close reading of a text to identify the hierarchical system and expose inconsistencies, contradictions, and underlying assumptions (Derrida, 1976; Rosenau, 1992; Lyotard, 1984). In this way, postmodernists focus heavily on language, discourse, and *metanarratives*, or the discourses that govern one's beliefs and actions in a social system (Hesse-Biber and Kelly, 2010), while recognizing that the meaning of words and language is continuously shifting and socio-historically located (Derrida, 1976; Lyotard, 1984).

Postmodernism is particularly relevant for qualitatively oriented mixed methods researchers (Hesse-Biber and Kelly, 2010). Although mixed methods researchers have applied postmodern approaches in other fields (e.g., O'Loughlin et al., 2004), it is infrequently explicitly applied in mixed methods educational research. Educational researchers can combine postmodernism with mixed methods to deconstruct common myths about teaching and learning (Slaughter, 2001). Such researchers could ask research questions about what messages are embedded in policies and practices (Hesse-Biber and Kelly, 2010) in schooling, such as in dress code or bullying response policies, and how those messages impact students and teachers.

Dialectical pluralism

Dialectical pluralism has been referred to as a philosophical stance, paradigm, and metaparadigm (Greene and Caracelli, 2003; Greene and Hall, 2010; Johnson, 2017; Shannon-Baker, 2016; Tashakkori et al., 2021). I framed it here as a metaparadigm to showcase how it combines multiple philosophical paradigms, theoretical frameworks, and methodological approaches simultaneously (Johnson, 2017; Tashakkori et al., 2021). Dialectical pluralism emphasizes dialectical relationships among all frames within a research study, from methods to philosophical paradigms (Tashakkori et al., 2021). Dialectical pluralists believe in ontological pluralism, which posits that there are many ways to understand and perceive reality (Johnson, 2017). Knowledge is created through dialog between different perspectives in dialectical pluralism (Howes, 2017; Johnson, 2017; Plano Clark and Ivankova, 2016). Mixed methods researchers using this paradigm tend to emphasize dialog in data analysis, integration, interpretation, and writing (Plano Clark and Ivankova, 2016). For example, Shannon-Baker (2015) used this philosophical paradigm to inform the merging integration analysis of arts-informed, qualitative, and quantitative data in their study of students' experiences with culture shock during a study abroad program in a South American country for education majors. This paradigm also emphasized the importance of investigating divergence between the data sets during integration.

Yinyang philosophy

Mixed methods scholars have critiqued the Eurocentric discussion of philosophical paradigms in mixed methods research to show-case how yinyang philosophy from China aligns with mixed methods research thinking (Fetters et al., 2018; Fetters and Molina-Azorin, 2019). *Yinyang philosophy* is based on an ontology that embraces duality and the interconnectedness of elements. Within this philosophy, the researcher simultaneously holds that there is a singular and a dual reality, that multiple forms of knowledge are needed to understand a complex phenomenon, and that multiple methods need to be incorporated to achieve a balance of perspectives (Fetters, 2020; Fetters and Molina-Azorin, 2019). Although not an example specific to education, Knappertsbusch (2020) presents one of the few discussions applying yinyang philosophy to mixed methods research, describing how mixed methods integration aligns with this philosophy and the notion of *fractals*, which is a structure that contains smaller versions of the original. This philosophical paradigm offers a stance that emphasizes balance between perspectives and approaches that may be helpful for mixed methods educational researchers.

Indigenous philosophies

Indigenous researchers internationally have also critiqued the dominance of North American and Eurocentric perspectives on philosophical paradigms and mixed methods research (Chilisa and Tsheko, 2014; Martel et al., 2021). It is important to stress that specific philosophical beliefs and practices vary between different Indigenous communities. However, these philosophies generally share some similar characteristics. These characteristics include a recognition of Indigenous sovereignty; an embrace of the reciprocal relationship between humans, other animal species, the environment, the Land, and the spirit world; a focus on Indigenous voices and perspectives throughout the research process; and a disruption of colonial forms of knowledge and research (Chilisa and Tsheko, 2014; Martel et al., 2021; Smith, 2012). For example, Martel et al. (2021) argue that Māori worldviews, such as the metaphor of *he aua whiria* (braided river), support bicultural mixed methods research teams, like their own team comprised of Māori and New Zealand European researchers. Similar to the transformative-emancipation paradigm, their work describes an intertwining of multiple perspectives through the direct collaboration between Indigenous communities and non-Indigenous people (Martel et al., 2021).

Conclusions

As a mixed methods scholar, I fundamentally believe that philosophical paradigms influence all that we do, from designing a study to implementing and writing about it. The question is how that influence manifests and our intentionality around that influence. Exploring the differences and similarities among philosophical paradigms, like the discussion here introduces, provides mixed methods educational researchers one way to explore their own ontological, epistemological, and axiological beliefs and methodological practices. Seeking out manuscripts where researchers describe the influence of these beliefs on the research process will further elucidate the often intangible nuances to philosophical paradigms. How did their paradigm(s) influence the design, choice of sampling strategy, integration procedures, interactions with participants (or co-researchers), or how they presented their findings? Additionally, using the elements of philosophical paradigms to ask questions about the features of a study (published or one's own ongoing work) will further help to identify these hidden connections.

Introduction

Mixed methods research involves the intentional combination of quantitative and qualitative research approaches to generate nuanced and valid insights about problems of interest (Johnson et al., 2007). Although there is a long history of researchers and evaluators combining quantitative and qualitative methods in their studies (Maxwell, 2016), interest in this approach has flourished in the 21st century across disciplines and countries. Educational scholars have been at the forefront of this interest by advocating for the value of mixing methods to address educational problems (e.g., Johnson and Onwuegbuzie, 2004; Mertens, 2015) and advancing considerations for how to design and implement quality mixed methods studies (e.g., Creamer, 2018; Creswell and Plano Clark, 2018; Greene, 2007; Tashakkori et al., 2021).

As interest in mixed methods research has grown within education and beyond, an entire field has emerged that is dedicated to the advancement of mixed methods research practice (Plano Clark and Ivankova, 2016; Tashakkori and Teddlie, 2003, 2010). This field encompasses an international community of scholars, an extensive body of literature, and a way of thinking that explicitly values different kinds of knowledge. Despite its relatively recent development, the field of mixed methods research is notably complex and dynamic (Fetters and Molina-Azorin, 2017; Hesse-Biber and Johnson, 2013; Poth, 2018). The field grapples with all dimensions of research from philosophical foundations to design and procedural considerations to team dynamics and funding priorities. Furthermore, the field intentionally combines different research approaches often associated with different assumptions, disciplines, and conventions. Educational scholars, researchers, and practitioners need to navigate this complexity to understand and effectively apply mixed methods research to important educational problems of interest.

One way that scholars address complexity is to develop conceptual frameworks that simplify and organize key elements of complex ideas. In response to the complexity of mixed methods research, methodologists have developed conceptual frameworks that identify key concepts that make up the field of mixed methods research and describe the relationships among them. These frameworks can be very helpful for individuals interested in navigating the different dimensions and perspectives associated with mixed methods research practice. In particular, researchers, methodologists, practitioners, teachers, and policymakers interested in educational issues can benefit from using conceptual frameworks to guide their understanding of mixed methods research as it applies to their interests.

Therefore, the aim of this chapter is to introduce and distinguish different types of frameworks for conceptualizing mixed methods research and to illustrate how readers can apply a socio-ecological framework for mixed methods research. We first define conceptual frameworks and briefly consider their general utility. Next, we differentiate types of frameworks that describe mixed methods research. From there, we examine the socio-ecological framework for the field of mixed methods research and consider how readers can apply this framework within their own educational research practice. We conclude with comments about future work for mixed methods research frameworks and recommendations for educators engaging with mixed methods research practice.

Definition and utility of conceptual frameworks

Before considering conceptual frameworks that describe mixed methods research, it is helpful to first briefly define what we mean by the term conceptual framework. In a conceptual framework, the word *concept* has been defined as assumptions, expectations, theories (Maxwell, 2012), points of view (Imenda, 2014), ideas, perceived facts, beliefs, mental pictures, perceptions, or theories (Rallis, 2018). These conceptions describe the nature of a complex topic by breaking it down into the most important ideas. The word *framework* in this term has been referred to as a system (Maxwell, 2012), a model (Plano Clark and Ivankova, 2016), a basic structure, or underlying organizational elements (Rallis, 2018). That is, a framework identifies the key concepts about a topic and describes how they are thought to work in the real world.

Based on the definitions of concept and framework, we define *conceptual framework* as an analytical model, map, structure, or organization of concepts that serves to represent and describe a complex idea, phenomenon, or system in a simplified way. Sometimes a conceptual framework is also referred to as a theoretical framework (Hughes, 2019), or a theoretical model (Plano Clark and Ivankova, 2016). These alternative terms often are used to refer to the researcher's assumptions about the substantive topic for a study and provide the theoretical foundation that informs decisions such as research questions and hypotheses and data collection forms (Grant and Osanloo, 2014; Plano Clark and Ivankova, 2016).

Conceptual frameworks have been used as a helpful tool for researchers and practitioners to describe their work's organization to different audiences, such as readers or students. As such, they can benefit different groups of people in education. For teachers, a conceptual framework can help them to organize their teaching concepts, assumptions, ideas, and examples into a logical mind map. Such maps can give them a clear picture of the relationship of different course components and help them to plan and articulate the flow of each class. For example, an instructor could use Bloom's taxonomy of six cognitive domains (e.g., remember, apply, evaluate) to organize the content in a course on curriculum design within the online learning environment. For researchers, a conceptual framework enables them to organize different theories, arguments, methods, procedures, and evidence in a clear and visual manner during the planning of their study. This framework can provide them the opportunity to check if any part of the research needs to be modified before being implemented. For example, Bustamante (2019) used the Technological Pedagogical Content Knowledge theoretical model to inform the decisions about and interpretations of the quantitative and qualitative methods in her study of the professional development of teachers of Spanish learning a new technology. A conceptual framework can also facilitate readers' comprehension of a research study's logic and design. Methodologists can use conceptual frameworks to organize complicated ideas about a research methodology into comprehensive or summative models to make sense of the field for others and to identify different methodological areas in need of further development. For example, Crotty (1998) advanced a four-level model of the elements that inform all research studies (i.e., epistemology, theoretical perspective, methodology, and methods) and used it to explain the diversity of approaches applied by researchers.

Different types of conceptual frameworks that describe mixed methods research

As the previous section highlighted, conceptual frameworks can be highly useful tools within any complex topic area or field of interest. Therefore, it is not surprising that methodologists working in the field of mixed methods have developed many different frameworks to conceptualize and describe mixed methods research. We consider *mixed methods conceptual frameworks* to be models, maps, structures, or organizations of concepts that represent and describe key aspects of mixed methods research considered by the field and relevant to the methodological considerations associated with this complex approach. Some mixed methods conceptual frameworks are very specific, focusing on one narrow topical area such as sampling (e.g., Collins et al., 2007) or validity (e.g., Delinger and Leech, 2007). Others are very broad, such as describing the domains of the field as a whole (e.g., Greene, 2008). Each framework has been thoughtfully crafted for a particular intent and has utility for different stakeholders to understand and engage with mixed methods research practice.

The availability of many different conceptual frameworks that describe mixed methods research has great potential benefit for individuals who use mixed methods research in their educational practice. However, the presence of so many different frameworks, developed by different scholars for different purposes, can also be confusing, especially for those who are new to this methodological approach. Therefore, before considering any particular framework in depth, it is helpful to first consider the different kinds of frameworks that exist for mixed methods research so that readers can recognize the variations and better select a framework that is appropriate for their own mixed methods research practice needs.

The prominent mixed methods conceptual frameworks fall into four types based on the framework's purpose. These types are: (a) frameworks describing the process of a mixed methods research study, (b) frameworks describing prototypical mixed methods research designs, (c) frameworks describing validity in mixed methods research, and (d) frameworks describing the structure of the field of mixed methods research. Each framework type is briefly introduced in the sections that follow and an example of each framework type is depicted in Fig. 1.

(2021) framework describing MMR design options, (C) Dellinger and Leech's (2007) framework describing validity in MMR, (D) Greene's (2008) framework describing the structure of the field of MMR.

Frameworks describing the process of a mixed methods research study

When engaging with the mixed methods literature, readers are likely to come across conceptual frameworks that describe the dynamic process of doing a mixed methods research study (Creswell and Plano Clark, 2018). These frameworks highlight the different methodological decisions (or steps) involved when researchers are planning and conducting a study using mixed methods research and the interactions that occur among the decisions. These frameworks tend to conceptualize the research process as a dynamic system of choices and then describe how that process is adapted to mixed methods research. Many of these frameworks emphasize the research process by delineating major steps and how the steps fit together within a mixed methods study (e.g., Maxwell and Loomis, 2003; Plowright, 2011; Tashakkori et al., 2021).

There are many examples of frameworks describing the process of a mixed methods study in the literature. For example, Plowright (2011) introduced the Framework for an Integrated Methodology (FraIM) to discuss the process of mixed methods research. As depicted in Fig. 1A, he conceptualized the mixed methods research process involving eight connected steps. More recently, Tashakkori et al. (2021) used an input-process-outcome model to describe the stages of mixed methods research projects. In their model, the inputs include the study's background and purpose, the process includes data collection and analysis, and the outcomes include the results and conclusions. Other frameworks that describe the process of a mixed methods study are more conceptual in nature (e.g., Creamer, 2018; Hall and Howard, 2008; Long and Rodgers, 2017). For example, Creamer (2018) used a metaphor of an arch to describe the process of a mixed methods study. In her framework, the quantitative and qualitative components of the study are carefully constructed (like the two sides of an arch) to support integration and quality conclusions (represented by the keystone at the top of the arch).

Frameworks that describe the process of a mixed methods research study are very useful for understanding and applying mixed methods research within educational contexts. For educational researchers wanting to use mixed methods in their own research, these frameworks provide important guidance on how mixed methods decisions fit within the steps of the research process. For example, [Maxwell and Loomis' \(2003\)](#) interactive model helps researchers consider the linkages between their purpose, research questions, substantive conceptual framework, methods, and validity as they plan their mixed methods study. For educational practitioners and policy makers wanting to understand and learn from published mixed methods studies, these frameworks are also especially useful. Since mixed methods studies can be particularly complex to read because they often include two or more samples, types of data, and analytic procedures, a conceptual framework can help readers make sense of any mixed methods study in terms of its general process of research (such as its purpose, data collection and analysis, and results and conclusion). Readers interested in further discussion of these types of frameworks should see the chapter on dynamic approaches to designing mixed methods research by Maxwell.

Frameworks describing prototypical mixed methods research designs

The second type of framework was developed to delineate sets of different prototypical logics available for planning or comparing mixed methods research designs. These frameworks are often referred to as *design typologies* as they are made of different types of design logic ([Leech and Onwuegbuzie, 2007](#); [Teddle and Tashakkori, 2006](#)). As noted in [Fig. 1B](#), [Tashakkori et al. \(2021\)](#) provided an example of a design typology framework that includes four families of mixed methods designs (i.e., parallel, sequential, conversion, and hybrid) that describe different processes for implementing the quantitative and qualitative strands of a mixed methods study. As another example, [Creswell and Plano Clark \(2018\)](#) identified three mixed methods core designs in their framework based on the intent of the design (i.e., to explore, to explain, or to converge) and the sequence of qualitative and quantitative methods (e.g., sequential, concurrent). Each of these design prototypes can be depicted with a flow chart that demonstrates the timing of the application of each method (including data collection and analysis), and the point(s) when the results are mixed and interpreted. [Greene \(2007\)](#) categorized component design types (i.e., convergence, extension) based on research intent and integrated design types (i.e., iteration, blending, nesting or embedding, mixing for reasons of substance or values) based on mixing approach. [Morgan \(2014\)](#) highlighted the sequencing and priority options in his four core designs: qualitative input design, quantitative input design, qualitative follow-up design, and quantitative follow-up design. Interested readers can find a more in-depth discussion of design issues in the chapter on mixed methods research designs by Tajima.

Frameworks that describe typologies of different logics for mixed methods research can help researchers consider different possible options for their study and communicate their approach to others. In communicating with others, such frameworks can reflect the researchers' major emphasis and intent for using and integrating different types of databases ([Creswell and Plano Clark, 2018](#)). They also allow researchers from different fields to situate their studies within a specific domain of inquiry using mixed methods research ([Tashakkori and Teddle, 2010](#)). From a time-saving perspective, they also make researcher's work more efficient by providing different research approaches and sequence guidance for researchers to choose, to follow, and/or to modify based on their research purposes and resources.

Frameworks describing validity in mixed methods research

Frameworks describing validity aim to organize different methodological considerations necessary to assess the quality of mixed methods research. These frameworks have emerged in response to long-standing debates about what constitutes quality in mixed methods studies. Mixed methods validity remains one of the controversial issues in the mixed methods literature due to challenges associated with the need to appraise both the quality of the quantitative and qualitative study components and the validity of the derived mixed methods inferences ([Creswell, 2015](#); [Fàbregues and Molina-Azorin, 2017](#); [Teddle and Tashakkori, 2010](#)). A variety of the proposed quality standards and quality appraisal strategies can be also accounted for by a combination of contextual factors related to different quality standards in researchers' disciplines, prevalent philosophical paradigms and existing epistemological practices related to mixed methods research ([Collins, 2015](#); [Eckhardt and Devon, 2017](#); [Giddings and Grant, 2009](#); [Plano Clark and Ivankova, 2016](#)). The perspectives on how to assess the quality of a mixed methods study range from evaluating separately the methodological quality of the quantitative and qualitative study strands, to addressing quality concerns related to the integration of the methods in mixed methods designs, and to appraising the quality standards common to any research study ([Heyvaert et al., 2013](#)).

The existing frameworks combine these perspectives in unique ways offering different quality domains and evaluation criteria for appraising mixed methods studies. Despite using different approaches, these frameworks have an underlying common goal of inference quality, which is a criterion for considering quality of the meta-inferences as inductively and deductively derived conclusions from a mixed methods study ([Teddle and Tashakkori, 2003](#)). For example, [Onwuegbuzie and Johnson \(2006\)](#) described nine types of methods legitimization that researchers should consider to ensure inference quality during a mixed methods study process, whereas [Dellinger and Leech \(2007\)](#) approached mixed method quality from the perspective of construct validation of all study components to ensure inferential consistency of the conclusions (see [Fig. 1C](#)).

Since developing quality inferences from the integration of the quantitative and qualitative components is at the core of a mixed methods study, quality assessment is viewed as an ongoing activity spanning the whole study process from planning, design, and implementation to results interpretation and dissemination. Several validation frameworks provide a comprehensive set of assessment criteria that transcend all stages in a mixed methods study process. These include *Integrative Framework for Inference Quality* (Teddle and Tashakkori, 2009), *Comprehensive Framework for Assessing Quality of Mixed Methods Research* (O’Cathain, 2010), and *Critical Appraisal Framework for Quality in Mixed Methods Studies in Health Sciences* (Curry and Nunez-Smith, 2015). Some frameworks emerged that offer quality criteria related to specific characteristics of mixed methods designs, such as timing (concurrent or sequential) of the quantitative and qualitative components and their integration. For example, Creswell and Plano Clark (2018) described validity threats for core and complex designs, whereas Ivankova (2014) advanced quality criteria specifically related to sequential Quantitative → Qualitative design. Additionally, the Mixed Methods Appraisal Tool (MMAT) was developed to critically evaluate qualitative, quantitative, and mixed methods studies included within systematic mixed methods reviews (Hong et al., 2018; Pluye et al., 2009).

Despite different purposes and quality criteria, mixed methods validity frameworks have promised utility because they help researchers understand how to reduce inconsistencies between the inferences from the quantitative and qualitative study components and how to create credible meta-inferences from an entire study. Moreover, these frameworks recognize the complexity of the mixed methods research process and the critical role of integration in ensuring inference quality and inference transferability. When choosing a framework, researchers should consider its scope and focus, the feasibility of using the suggested evaluation criteria, and their own beliefs and related epistemological practices. For consumers of mixed methods research, validity frameworks offer tools to appraise the quality of the reported mixed methods studies in both the research process and outcomes. Readers interested in further discussion of these types of frameworks should see the chapter on quality in mixed methods research by Collins.

Frameworks describing the structure of the field of mixed methods research

A fourth type of mixed methods conceptual framework emerged as the field of mixed methods research has become more established and complex. This type includes frameworks developed to describe the complex structure of the field of mixed methods research as a whole. This type of framework specifies large conceptual domains of interest to the field and uses those domains to explain how the field of mixed methods is organized. Such frameworks serve to define the field of mixed methods and its primary topical areas of consideration. Several frameworks have delineated a small set of three to five core domains to describe the field, which have been referred to as “methodological domains” (Greene, 2008, p. 7), the “developing landscape” (Creswell, 2010, p. 46), and “overlapping components” (Teddle and Tashakkori, 2010, p. 3). For example, as depicted in Fig. 1D, Greene (2008) described the field of mixed methods research in terms of four large methodological domains: philosophical assumptions and stances, inquiry logics, guidelines for practice, and sociopolitical commitments. Plano Clark and Ivankova (2016) advanced a socio-ecological framework that identified components of the field and organized them into interconnected levels to depict how the components and levels interact with each other. More recently, Fetters (2018) conceptualized the field into six different equations that capture the “compelling issues” (p. 262) of interest to the field.

The previously described frameworks conceptualized mixed methods research in terms of decisions and options related to a specific aspect of mixed methods research practice. In contrast, the frameworks for describing the structure of the field are broader and more conceptual in nature. These frameworks serve to identify and make sense of the many domains and perspectives found within the field of mixed methods research. Due to their breadth, they can be especially useful for understanding, applying, and assessing the field of mixed methods research as a whole. For researchers who are new to mixed methods research, frameworks describing the field’s structure provide a useful introduction to the main conversations occurring in the field. Simply put, they are a quick way to learn what members of the field are talking and writing about so the ideas can be applied in one’s research applications. For consumers who are working to learn and understand mixed methods research, these frameworks facilitate recognizing the major topics of interest in the field and identifying how different sources from the literature fit among those major topics. Relatedly, these frameworks are also useful for making curricular decisions for instructors who are teaching about mixed methods research. Furthermore, methodologists interested in the advancement of mixed methods use these frameworks to assess the status of the field, including what is known and what remains unknown within major domains.

Summary

Each of the types of frameworks we have highlighted plays an important role in mixed methods research. Readers can benefit from identifying and applying all the types. The first step, however, is to be able to recognize that there are different kinds of frameworks and that each framework is developed for its own purpose and intent. From there, readers can apply selected frameworks in their mixed methods research practice in a multitude of ways. In the next section, we highlight one specific mixed methods conceptual framework and provide examples of different ways that it can be applied within one’s educational and research practice.

Application of one framework for the field of mixed methods research

Across the many mixed methods conceptual frameworks that are available (and continue to be developed), frameworks for describing the structure of the field of mixed methods research are unique in terms of their scope and applicability. Therefore, we have selected one specific framework to examine in more depth, namely the *socio-ecological framework for the field of mixed methods research* introduced by [Plano Clark and Ivankova \(2016\)](#). We provide an overview of this framework and then consider four different ways that it can be applied within educational contexts.

Overview of the socio-ecological framework for the field of mixed methods research

Recognizing the growing complexity of the mixed methods field and the dynamic relationships that exist among its different components, [Plano Clark and Ivankova \(2016\)](#) advanced a comprehensive framework that would help researchers and consumers navigate the mixed methods field. They described the mixed methods field from a socio-ecological perspective that recognizes the existence of the interwoven dynamic relationships between the various individual and environmental factors, such as personal, interpersonal, organizational, community and societal contexts ([Bronfenbrenner, 1979](#); [Stokols, 1996](#)). The framework aims to identify key mixed methods methodological considerations and contextual domains of interest to the field and explain how the considerations and contexts influence researchers' approaches to designing and implementing mixed methods studies.

The framework for the mixed methods field takes the form of a socio-ecological model of hierarchical interconnected levels and their components consisting of the mixed methods research process, mixed methods research content, and mixed methods research contexts (see [Fig. 2](#)). The mixed methods research process occupies the central position because it provides the foundation for any mixed methods study through the formulation of the research purpose and questions, selection of methods, and creation of inferences (see the central box in [Fig. 2](#)). The mixed methods research process is nested within five methodological domains, which form the mixed methods research content (see five overlapping inner circles in [Fig. 2](#)). These methodological domains represent the decisions that researchers have to make about the mixed methods research process and include the definitions of mixed methods research, the rationales for using mixed methods in a study, the mixed methods design logics, the criteria for assessing quality in mixed methods research, and mixed methods intersection with other approaches and designs. In their turn, these domains are shaped by three interconnected mixed methods research contexts: personal, interpersonal and social contexts (see three nested outer circles in [Fig. 2](#)).

Fig. 2 [Plano Clark and Ivankova's \(2016\)](#) socio-ecological framework for the field of mixed methods research (MMR). Figure is reprinted with permission of Sage Publishing from [Plano Clark and Ivankova \(2016\)](#).

Mixed methods personal contexts include researchers' philosophical assumptions, theoretical models, and background knowledge. Interpersonal contexts are comprised of interpersonal relations and ethical considerations with study participants, research teams, and reviewers. Social contexts are institutional structures, disciplinary conventions, and societal priorities with regards to mixed methods research. These contexts jointly influence researchers' choices of methodological decisions related to five mixed methods content domains resulting in a variety of ways how researchers approach the research process in mixed methods studies.

The socio-ecological framework for mixed methods research has several advantages for educational research practice. This framework is the most comprehensive framework in the field of mixed methods research and can be applied in many ways to understand, describe, and explain different components of the mixed methods research practice. Moreover, the socio-ecological perspective provides the mechanism for applying mixed methods research to study complex educational issues by helping researchers position themselves regarding mixed methods research and make methodological decisions that align with the research questions of interest. The interactive and dynamic nature of the framework allows consumers of research to better understand the variety of perspectives on mixed methods across disciplines, research topics, and practices, thus helping them make sense of the methodological and empirical mixed methods writings. Its comprehensive nature also makes it useful for teaching and learning about mixed methods research. In the following sections, we illustrate how the socio-ecological framework for mixed methods research can be applied in educational research and teaching practice.

Application of the framework to organize the literature about mixed methods

The field of mixed methods has expanded into an extensive collection of literature that covers many topics written by many different scholars. There are thousands of articles and hundreds of books and chapters available to read that discuss mixed methods research. Some of the literature describes different applications of mixed methods research and some provides insights into the methodology. The extensive nature of this literature can quickly become overwhelming for readers, particularly those who are new to mixed methods research. It can be a challenge to make sense of individual readings and identify how they are similar to and differ from other readings.

One of the most useful features of any conceptual framework is that it identifies key domains for the phenomenon of interest, which can be applied to organize information. Education scholars and practitioners who are reading literature about mixed methods research can apply the domains from the socio-ecological framework for mixed methods to help them make sense of and organize that literature. For example, [Plano Clark and Ivankova \(2016\)](#) used the nine domains in the model (as identified in [Fig. 2](#)) to organize their book about mixed methods research by writing a chapter for each domain. Likewise, readers can use the nine domains (or just the three levels of process, content, and contexts) to classify the primary topics of their readings about mixed methods.

An example can illustrate this strategy. A reader interested in mixed methods research might encounter the following two articles: (a) *Dialectic Dialogue: Reflections on Adopting a Dialectic Stance* by [Cronenberg and Headley \(2019\)](#) and (b) *Multilevel Mixed Methods Research Designs: Advancing a Refined Definition* by [Headley and Plano Clark \(2020\)](#). These two articles happen to share a common author, but each fits into a different domain within the field of mixed methods research. First, educational researchers [Cronenberg and Headley \(2019\)](#) wrote about their use of a dialectical philosophical stance while conducting their mixed methods dissertations. Using the socio-ecological framework, readers could make sense of this article as fitting within the contextual domain of personal contexts for mixed methods research. Second, educational researchers [Headley and Plano Clark \(2020\)](#) wrote about the definition of multilevel mixed methods designs, using several examples from education to highlight the utility of such designs. Using the socio-ecological framework, readers could make sense of this article as fitting within the content domain of mixed methods research designs. Distinguishing these two articles by these larger mixed methods domains can be helpful for readers to distinguish the topics of these two methodological writings. As readers engage with additional literature about mixed methods, a helpful strategy is to develop folders for organizing the different sources into topical domains to facilitate understanding and retrieval of information later. This strategy can be facilitated by applying the domains identified within the socio-ecological framework to organize this literature.

Application of the framework to understand a published mixed methods study

Another challenge in mixed methods research is for readers to understand published reports of mixed methods studies. Because mixed methods approaches are well suited to address complex topics, they are becoming increasingly common for examining issues relevant to education. Therefore, no matter the particular educational area of interest, readers are likely to encounter reports of studies that used mixed methods approaches. Through the combination of quantitative and qualitative methods within the studies, the results and interpretations of these studies can provide readers with comprehensive and nuanced insights. However, because mixed methods studies include quantitative, qualitative, and mixed methods aspects, the published reports of these studies can be a challenge to understand. One way to address the challenge of understanding a published mixed methods study is for readers to use the socio-ecological framework to identify specific mixed methods elements occurring within the study and map out how they are related to each other.

Fig. 3 Application of the socio-ecological framework for understanding a published mixed methods study. Figure based on Plano Clark and Ivankova's (2016) Socio-ecological Framework for Mixed Methods Research (MMR) and the study report published by Clark and Plano Clark (2019).

Fig. 3 is an example of how the socio-ecological framework can be applied to understand the design and implementation of a mixed methods study about grit in the context of career success (Clark and Plano Clark, 2019). The study's mixed methods research process is portrayed in the center of Fig. 3. Clark and Plano Clark designed the study using two sequential phases starting with a quantitative phase and then connecting to a qualitative phase. The uppercase letters indicate the priority of the quantitative phase for addressing the study's purpose. In the quantitative phase, the researchers gathered data from 423 working adults using an online survey. The researchers used statistical procedures to test the hypothesized positive relationship between grit and career success, and the results found no significant relationship. From there, they interviewed five individuals who were purposefully selected because they scored high in terms of both grit and career success to better understand the role of grit within their careers. The two sets of results were integrated in the end to provide novel insights into how grit manifests within the career context.

The five overlapping circles around the research process box in Fig. 3 highlight the mixed methods research content considerations that informed the mixed methods research process of Clark and Plano Clark's (2019) grit study. These considerations included defining mixed methods as the "intentional administration" (p. 94) of both quantitative and qualitative methods to understand a problem; having a rationale of using the qualitative phase to complement and explain the meaning of quantitative results; applying the logic of a sequential (QUAN → qual) mixed methods design; and using strategies to ensure the validity of the quantitative results and the credibility of the qualitative findings. The three outer circles found in Fig. 3 describe the interrelated mixed methods research contexts that shaped the study. For example, the authors' personal contexts included their alignment with the assumptions of positive psychology and training in mixed methods research. Interpersonal contexts included gaining approval for the study from the university's ethical review board and recruiting working adults to participate in the two phases of the study. Social contexts included disciplinary considerations from both education and psychology and the acceptance of mixed methods within the university program. By mapping out the mixed methods research process, content considerations, and contexts in this way, readers can have a good understanding of the major elements found within any mixed methods study.

Application of the framework to articulate one's positionality for mixed methods research

The previous section demonstrated how the socio-ecological framework for mixed methods research can be applied to identify the influential contexts and considerations found within a published mixed methods study. In addition to being able to describe others' mixed methods research, it is important for educational researchers to articulate their own positionality for mixed methods research. Much of the complexity found in mixed methods research can be attributed to the fact that scholars interested in mixed methods research come from different contexts and have different viewpoints about the considerations relevant to mixing methods. When engaging with mixed methods research practices, individuals benefit from articulating their own perspectives about mixed methods in addition to recognizing the perspectives of others.

The socio-ecological framework for mixed methods research provides a useful framework for describing one's mixed methods viewpoints. We have provided questions in [Table 1](#) that are aligned with the framework and may be helpful for individuals to answer as they articulate their own positionality. Starting from the outer-most layers depicted in [Fig. 2](#), individuals should recognize the social, interpersonal, and personal contexts that they bring to their thinking about the use of mixed methods research by answering the questions in the first section of [Table 1](#). Next, we encourage individuals to articulate their position relevant to the major context considerations for mixed methods research. The context consideration domains are depicted in the five overlapping circles within [Fig. 2](#) and corresponding questions appear in the middle section of [Table 1](#). Finally, individuals can describe their ideas about the mixed methods research process by answering the questions in the bottom section of [Table 1](#). For educational researchers, these answers might pertain to a specific study, but they can also be answered generally for anyone interested in educational issues informed by mixed methods research practices. Collectively, individuals can identify and describe their position within the field of mixed methods research and connect this position to their mixed methods research practice by addressing each of the domains found within the socio-ecological framework. [Sanders \(2021\)](#) used this approach when describing her positionality in the context of her dissertation study involving Black women faculty in higher education within the United States. As shown in [Fig. 4](#), she used the framework to articulate her perspectives about "ways Black women faculty and their lives are intertwined historically, interpersonally, and socially as it relates to their presence and work in higher education" (p. 18) along with her assumptions about the use of a mixed methods approach.

Table 1 Applying the socio-ecological framework for articulating one's positionality for mixed methods research.

Level	Domain	Example questions to answer
MMR contexts	Social contexts	• In what ways is MMR supported by your organization? • What is the status of MMR in your specific disciplinary area? • To what extent is MMR supported by relevant funding mechanisms?
	Interpersonal contexts	• How is MMR understood by your human subjects review board? • How will MMR be received by potential participants? • What different perspectives about research are represented within your partners and team members?
	Personal contexts	• How open are gatekeepers to the use of MMR? • What assumptions do you hold about the nature of knowledge and how MMR can contribute to knowledge? What philosophies help to describe these assumptions? • What assumptions do you hold about how your educational topic works? What theories help to explain these assumptions?
MMR content	MMR definitions	• What training and prior experiences inform your thinking about MMR?
	MMR rationales	• How do you define MMR? What literature informs this definition?
	MMR designs	• What are your reasons for using MMR? What literature informs this rationale? • What is your approach to thinking about MMR designs? What literature informs this design thinking?
	MMR and other approaches	• What other approaches to research are you using? How might this approach combine with MMR? What literature informs this combination?
MMR process	MMR quality	• What is your approach to assessing quality in MMR? What literature informs your quality standards?
	Process elements	• What research questions are of interest to you?
		• What quantitative and qualitative methods are best for addressing these questions? How can/will the two methods be used in combination? • What kinds of insights can be gained by combining the methods?

Note: MMR = mixed methods research.

Information based on [Plano Clark and Ivankova \(2016\)](#).

Fig. 4 Application of the socio-ecological framework for mixed methods research (MMR) to articulate a researcher's positionality. © Sanders (2021), figure is reproduced with permission of the author.

Application of the framework to plan teaching about mixed methods research

The growth of the mixed methods field in both the volume of mixed methods studies and their complexity creates significant challenges for learning about mixed methods research. These challenges are prompted by several factors. The field of mixed methods research is relatively new and embraces a variety of perspectives on what constitutes mixed methods, the rationales for using it, the choice of mixed methods designs, and the quality of the generated findings, to name a few. Moreover, researchers' use of mixed methods is often shaped by the epistemological approaches prevalent in their disciplines, which results in observed variations in how mixed methods studies are designed and conducted. Understanding and navigating the realm of different mixed methods perspectives and practices can be a daunting task for emergent scholars who range from consumers of mixed methods research to researchers planning to apply mixed methods in their studies.

The socio-ecological framework for mixed methods provides instructors with a pedagogical tool to conceptually organize learning about mixed methods around its methodological domains and influencing contexts. For example, [Ivankova and Plano Clark \(2018\)](#) used the framework to structure their Introduction to Mixed Methods Research course. The goal of the course is to provide students with foundational knowledge about mixed methods research and its fundamental principles and to introduce students to the major perspectives on the application of mixed methods. The course is organized around the framework domains starting with the process of mixed methods research and exploring how the different perspectives within each methodological domain shape researchers' approaches to applying mixed methods to research problems of interest. The influencing role of the three

contexts is then explored with a special emphasis on students' understanding of the dynamic interrelationship of all levels and components of the framework in their joint impact on the mixed methods research process. In addition to didactic knowledge, students learn to apply the framework domains to synthesize and critique different perspectives found in the literature about the methodological aspects of mixed methods research.

Concluding comments

In this chapter, we introduced different types of mixed methods conceptual frameworks and highlighted the socio-ecological framework for mixed methods research in educational practice. These frameworks are well-suited to enhance one's understanding of the complexity of mixed methods research in different ways. It should be noted that each type of conceptual framework illustrates an aspect (e.g., process, logic) of a mixed methods project or specific mixed methods topic (e.g., the structure of the field) that needs to be summarized, introduced, or clarified. Therefore, before adopting a conceptual framework, it is important to decide which aspect of mixed methods research needs to be elaborated. Remember that each framework is a tool, and each tool serves the best when being used in the right place and the right way.

In addition, as research and educational practice keep evolving, new aspects of mixed methods research will keep emerging, so will the conceptual frameworks. As researchers, instructors, and practitioners across many disciplines, including education, continue to expand their thinking about and application of mixed methods research, we expect that additional conceptual frameworks will be warranted. We can imagine that future frameworks may emerge to describe the increasing complexity of mixed methods research as it incorporates new data forms (e.g., social media, position tracking data), analytic approaches (e.g., machine learning, social network analysis), and stakeholders (e.g., policy makers, community members). Therefore, as much as we hope our chapter serves as an information tool box, we also hope it serves as an inspiring stepstone for our readers to step on to adopt, modify, and innovate conceptual frameworks for better conceptualizing mixed methods research for others.

Finally, we recommend a few resources as a quick-start for our readers who are interested to explore more about conceptual frameworks that describe mixed methods research.

Transformative mixed methods research

Educators face many challenges in their attempts to provide quality education to all learners. Although educators are not responsible for solving all the ills of society, they can be part of the solution by recognizing the historical inequities and current conditions that influence their abilities to provide needed educational services. For example, the Roma population in Europe are recognized as a population that has experienced multiple discriminations in the form of slavery, expulsions, persecutions, genocide, and criminalization (Flecha, 2014). A school in Albacete, a city in Spain, served the Roma population in a neighborhood that was conflict-ridden; teachers reported feeling threatened entering the school; and the media blamed the Roma. Flecha and his colleagues asked the question: How can educational research contribute to improved academic achievement, a safer environment, social inclusion, and empowerment? They adopted a transformative framework for their research because it is characterized by challenging existing power relationships, explicitly addressing the basis of discrimination, and creating data that support positive transformative change. The use of mixed methods within this framework allowed them to collect data that were responsive to the cultural context and inclusive of the voices of the full range of interested parties.

The transformative lens for research arose as a response to concerns raised by members of marginalized groups that they felt they were either not included appropriately or were misrepresented in research (Mertens, 1999, 2018, 2020a; Mertens and Wilson, 2019). Members of these communities have expressed their experience with research as either leaving them worse or no better off and have developed a high level of skepticism about the value of research. For researchers to contribute positively to change in communities, researchers need to critically examine the research assumptions about what makes for ethical research, the privileging of accepted versions of reality, the relationship between the researcher and participants, what is valued as knowledge, and the appropriateness of methodologies to support transformation. This is the core of the transformative approach to mixed methods. Following the explanation of the assumptions associated with a transformative approach to mixed methods, this chapter includes a description of multiple examples that illustrate its application in pursuit of increased justice for members of marginalized communities.

Assumptions associated with transformative mixed methods

The ethical assumptions that embody a transformative approach raise questions such as: What methods are needed in order to be culturally responsive to the full range of participants and those effected by the research? How can the research be designed to promote social justice and further human rights? How can the research explicitly deal with historical and current discrimination in order to reduce inequities? How can communities be engaged in ways that incorporate their strengths and resilience so that they are better off as a result of their participation (Mertens, 2020a)? Such questions provide opportunities for researchers to design studies that go beyond “giving voice” to members of marginalized communities to enable the needed transformative change and create conditions that lead to a more just and equitable society (Cook, 2014).

In 1903, W.E.B. Du Bois asked the question: “How does it feel to be the problem?” (1903/2003, p. 7) He was writing about the tendency in the United States to blame Black people for the inequitable conditions in which they live and the negative consequences of living in poverty, sometimes associated with high rates of violence. His words have a striking similarity to the example provided by Flecha’s (2014) study cited earlier: The Roma are the problem. Ontological assumptions relate to the understanding of the nature of reality. One version of reality that is sustained by an oppressive status quo is that members of the marginalized communities are the problem. The use of a transformative lens asks researchers to examine the social positionalities associated with different versions

of reality and to design research that reveals versions of reality that sustain an oppressive status quo, as well as to reveal those versions that contribute to a positive transformative future. For example, research designed to smooth the transition of youth involved in the criminal justice system back to school hit a snag when the researchers found that some of the school personnel were not supportive of the program (Drill et al., 2017). The school administrators held a version of reality that characterized the returning students as troublemakers and that the transition program was “dumping students off” (p. 38). The researchers needed to use a research lens that allowed them to collect data about this version of reality and its consequences, as well as make visible the version of reality from the transition team about the support services needed for successful transitions. A transformative, culturally responsive lens allowed them to document both versions of reality and follow through on the consequences of allowing an oppressive version to prevail.

The transformative epistemological assumption pertains to the relationship between the researcher and participants, as well as to the nature of knowledge. It raises the questions: Whose knowledge counts as valid and what kind of relationships allow for the respect of knowledge from marginalized communities? This assumption bears close relationship with the transformative ethical assumption regarding the need to be culturally responsive. Methods are needed to increase understanding of the history and context in order to get an accurate picture of the heterogeneity of the communities in the studies. The dimensions of diversity that are relevant are contextually dependent. For example, in many high poverty areas in India, girls are valued less than boys; this is used to justify denial of their rights to education. In Malaysia, many Deaf people are not allowed to attend school and thus read poorly or not at all (Wilson and Winiarczyk, 2014). The 2019–2020 pandemic has revealed gaps in access to education as many school systems changed to online instruction, with people from lower socio-economic status and students of color experiencing less access. A complicating factor is the ability of some parents to be home to support their children’s instruction. Many parents work at jobs in which they have to be physically present (e.g., grocery store clerks, nurses, postal carriers, sanitation workers). Oftentimes, parents with lower incomes both have to work to maintain their ability to provide the necessities of life. Worldwide, communities of color experience a larger gap in their ability to access online instruction (UNICEF, 2020). As this situation illustrates, attention to data that depicts the characteristics of relevance associated with power or marginalization is critical in order to support inclusion of all community members. The transformative epistemological assumption supports inclusion in culturally respectful ways of members of marginalized communities, as well as those who hold more power. It also supports valuing the knowledge and experience of all relevant community members and calls for the use of methods that are capable of accurately capturing the experiences of people who are marginalized.

The transformative assumptions of the nature of ethics, reality, knowledge and relationships guide methodological choices that can lead to respectful relationship building, contextual and historical understanding, and collection and use of data for transformative purposes. A cyclical design exemplifies one transformative mixed methods approach (See Fig. 1) (Mertens, 2018, 2020a; Bolinsson and Mertens, 2021). The first cycle includes identifying who needs to be included and how they can be included in respectful ways. This might include literature reviews, individual consultations, focus groups, review of extant data on demographic characteristics and school achievement, or group meetings to determine who is present, who is not represented yet, and strategies for working together. The second cycle would focus on a more thorough contextual analysis that could include collection of data from surveys, review of historical documents, community characteristics, and legal issues, as well as a more focused approach to extant data, e.g., on success rates transitioning from the criminal justice system to school. The third cycle would make use of the data collected in the first two cycles to determine what type of intervention might be appropriate to address the identified problems.

Fig. 1 Transformative mixed methods iterative cyclical approach.

Data collection during this phase would be intensive and would provide feedback to the program developers about adjustments that might be needed to improve recruitment, training, and the quality of the program implementation and results. If the data support moving forward, a fourth cycle could be used to study the implementation of an intervention on a wider scale. The fifth cycle would include collection of data on the effects of the intervention and the quality of the relationships that were formed during the first cycle. The final phase would be to determine the effectiveness of the intervention. The cycle is viewed as iterative as each stage informs the next and any stage can be re-visited based on what is learned in the prior stages. Use of the processes, experiences, and results of the research for transformative purposes can occur throughout the research process, e.g., to improve the intervention, expand dissemination, improve relationships, or change policy.

Mixed methods provide opportunities to gain understandings of the complexity of populations and contexts so that appropriate interventions can be designed and tested. The specific designs and methods used in a transformative mixed methods studies are inclusive of many of the designs and methods used in other paradigmatic frameworks (e.g., pragmatism). However, it does lead the researcher to ask different kinds of questions in the determination and implementation of a design. For example, if a researcher decides to use a randomized controlled trial as a part of a transformative mixed methods design, a transformative lens would lead to questions such as: “Who would easily access and benefit from this treatment? What additional investments would be required to make this treatment accessible to all? What cultural practices enable the adoption of this treatment, and what adjustments might be made to make receiving the treatment more culturally accepted?” (Mertens and Catsambas, 2022)."

Application of transformative mixed methods design

Transformative mixed methods have been used across the globe with many different populations. These studies have focused on people with disabilities, Deaf people, women and girls, members of the LGBTQ+ community, people of color, Indigenous populations, internally displaced persons, undocumented and refugee students, and children in high poverty areas and areas of conflict. The examples presented in this section illustrate the application of transformative mixed methods through an analysis of a number of studies with various marginalized populations in diverse locations.

Gender-based violence: heteronormativity and LGBTQ+

Sexual violence is a worldwide problem that occurs in schools and elsewhere (DeGue et al., 2012). Efforts to address this problem have occurred at all levels of education and have taken a number of different forms. Some programs educate girls and women on how to avoid threatening circumstances while others educate boys and men on the valuing of women and intervening when sexual violence is threatened or bragged about. Puigvert et al. (2019) conducted a transformative mixed methods study to address gender-based violence in Spanish universities that did not distinguish between heteronormative participants and members of the LGBTQ+ community. Their approach utilized a communicative methodology that aligns with the transformative approach in that it “entails the assessment of actual social improvements related to research outcomes by collecting data and engaging in dialog with manifold stakeholders (p. 362).” They conducted the study over several years. They described their methods as having two phases: first, they identified key informants and faculty and students, and established a safe environment for their participation. Then they examined contextual issues related to gender-based violence in universities. The second phase used the communicative method to evaluate the social impact of their study to reveal the transformations that occurred.

In the first phase of the study, the researchers began with a literature review of historical and current status of gender-based violence and interventions strategies for prevention and response. However, their approach incorporated transformative methods by including review of literature that specifically addressed wider issues of inequality in this context and the “mechanisms and policies regarding the role of the state, social movements, and other agents involved in fighting against violence in 10 European countries (p. 363).” They examined Spanish legislation related to gender-based violence and women’s rights, as well as historical attempts to address this issue in universities through mobilization and using the universities’ committee structures. They concluded that there was a culture of silence, people knew who the perpetrators were but no one dared to report them. They directly confronted issues of power and they collected data from social networks on the oppressive tactics of powerful university administrators and faculty to silence the researchers and their students by threatening their academic careers. They formed relationships with senior faculty as well as with students, nontenured faculty, and staff in order to be able to conduct dialogs that were safe and informative. They also conducted a survey of students to determine the extent of gender-based violence in Spanish universities and what steps could be taken to overcome this violence. This was followed by conducting semi-structured in-depth interviews with faculty and administrators to obtain a more thorough picture of the situation. Students participated in communicative dialog sessions in which they reflected on the results of the survey; they reported lack of recognition of gender-based violence, institution resistance to address this issue, and the absence of mechanisms to respond to this reality. All participants identified the need for safe spaces, support, and the need for a public debate to stimulate change.

The second phase of the study began with widespread dissemination of the results of the first phase through multiple methods, such as dialogs in diverse settings in the university, professional presentations, publications, and documentary film. The dissemination activities were complemented by conducting additional communicative dialogs with key informants (faculty and students) to obtain data about the repercussions of acting as social agents of change and the extent to which Spanish universities had become safer spaces.

The transformations that resulted from their study included generating new legislation, creating proper conditions for reporting abuse, and establishing solidarity with and among victims with the goal of achieving violence-free universities. The transformations

were enabled by engagement with a wider range of constituencies that resulted in mobilization of students around this cause, the establishment of peer-to-peer support networks, and solidarity between faculty and students committed to further action on gender rights. This formation of coalitions to be party to the research and to carry on with the transformative changes needed has become an important part of the transformative research process, not just in this study, but also in many projects funded by the US government (Wolfe et al., 2020).

Zea et al. (2014) provide an example of a transformative mixed methods study that focused on gay and bisexual men and transwomen in Colombia, South America. They described the process of building relationships with members of this community so that the participants felt safe and respected before any data collection began. They gathered qualitative data on the culture that was rife with hegemony for members of this community, as well as on resistance from political and church officials. They conducted qualitative life-history interviews with participants that covered such topics as: "childhood, adolescence, family life, sexual orientation development, gender identity, experiences of discrimination and stigma, experiences of internal displacement and violence, sexual risk, sexually transmitted infections, HIV status, and knowledge and attitudes toward circumcision" (p. 215). Based on the data from the life-history method, they constructed a quantitative survey that was administered in a safe space, a community center recently renovated for this population to safely gather. The results were shared interactively with activist groups, representatives of the Colombian government health sector, and international organizations working on HIV/AIDS in Columbia with the intent of changing policies for this marginalized community.

People of color

Inequalities associated with being a person of color are widespread; addressing these in an educational setting is fraught with challenges (Neubauer et al., 2020). Several researchers have used a transformative mixed methods approach to address inequalities based on racial or ethnic status such as Machimana et al. (2018) study of university engagement with rural communities in South Africa and Mertens' (2020b) study of the reduction of gang violence in school neighborhoods in Trinidad. The example used in this section expands on the study of the transformation of a school in Spain that was conducted by Flecha (2014) that was mentioned at the beginning of this chapter. The study is situated in an underprivileged neighborhood with many Roma families and was structured to include Roma at a grassroots level in a longitudinal 5-year study. The study began with discussions with Roma and non-Roma families, teachers, school administration, the researchers, policy makers and other stakeholders. They conducted observations and interviews with these constituencies to develop a picture of student and teacher experiences.

They developed a plan to shut down the dysfunctional school and open up a new one in the same building. The community members were involved in the development of the intervention through interactive dialogs in which researchers provided information about successful educational practices. These practices were adapted to fit the specific context based on community feedback. Community members initially expressed skepticism about the project, but through concerted effort, trusting relationships were built. A case study design was used that incorporated the collection of quantitative data on achievement and satisfaction, as well as qualitative data on the quality of the experiences and wider influences on health and employment. One important component of the study was the establishment of an advisory council. Membership on the council included members of the most vulnerable groups, those who had a higher education degree, and those who had experience overcoming inequalities through community participation and social and political involvement. Data were collected at regular meetings of the advisory council that guided decisions about the future stages of the research.

Every year for 4 years, the researchers collected quantitative data about school attendance and achievement as well as the quality of experiences through two questionnaires given to students and families. Leaders in the Roma community took responsibility for distributing the questionnaires to local people, especially those who were most isolated. Qualitative data were collected using four methods. Community activists, school administrators and professionals participated in standardized open-ended interviews to determine their professional experiences. Communicative daily stories were collected from family members and students that included personal reflections and perceptions of daily life through a conversational format. Focus groups were used that allowed groups to reflect on findings from the study. Observations were also conducted that allowed researchers to ask participants what they observed and experienced. The researchers' choice of observation spaces was informed by information provided by Roma leaders and community members who had valuable information about the school, neighborhood, history of socioeconomic problems, and relationships with the local administration. The researchers modified the instruments for quantitative data collection and the qualitative protocols every year of the study based on input from community members.

The data were analyzed to address this question: "How was it helping to reduce or prevent inequalities and marginalization and fostering social inclusion and empowerment?" (p. 250) Transformative changes were evident throughout the study. For example, a new school was developed and implemented; family participation in the school increased over the five years; student achievement increased in language and mathematics; families and students expressed higher levels of satisfaction with their progress. Active participation in decision making yielded more support for the schools, better experiences for students, increased health in family relationships, higher literacy rates for families overall, and further positive effects in terms of housing, health, employment, and social and political participation.

Refugees and immigrants

Immigrants cross borders, sometimes legally and sometimes illegally, often to escape intolerable conditions characterized by violence, poverty, and starvation. Sometimes undocumented immigrants are brought to the United States as children where they have lived the majority of their lives with a constant fear of being sent back to their birth country, even though they have no

familiarity with that country. In the United States, a great deal of turmoil emerged as the number of undocumented immigrants increased in the last decade, resulting in separation of families and deportation of many asylum seekers. [Barnhardt et al. \(2018\)](#) conducted a transformative mixed methods study that examined how campus administrators navigate the process of serving undocumented immigrant students in the Southeastern United States. They chose this approach because they saw a need to apply a research approach that contributes to understanding how the oppression of vulnerable populations is institutionalized in university settings.

The researchers began by collecting contextual data about immigration legislation and policy in the United States and how it is applied by local authorities. They documented the different versions of reality, some of which lead to oppression for undocumented students. They looked proactively at how transformative change could lead to changes in practices to be more inclusive and supportive. They focused on administrative processes because they were aware of the power structures that enable an oppressive status quo to continue. "Our unique focus on collective and organizational processes helps illuminate the multiple and competing ways in which institutional power and organizational power (or lack thereof) manifest when enacted by campus administrators and leaders operating in a particular localized cultural context (p. 414)." They continued: "transformation also emerges from disrupting structural and institutional oppression that can be addressed by understanding complex cultural realities and organizational responses to them (p. 415)."

The researchers began by forming a partnership with campus professionals at campuses across the Southeastern United States. The team included a lifelong activist in the undocumented student movement, campus administrators and educational researchers. This initial partnership identified a need to conduct a contextual analysis to identify the uniqueness of the local environments in terms of culture, political variables, power structures and economic status.

The researchers reviewed academic literature on organizational responses to contentious issues to gain insight into how an organization takes an ethical stand with regard to social responsibilities. They also analyzed federal and state policies to identify the barriers experienced by undocumented university students, such as banning such students from attending state or public universities, or lack of access to in-state tuition or obtain financial aid. In the United States, out-of-state tuition can be up to two to three times higher than in-state tuition, resulting in an increase of an average of \$8500 US ([National Center for Educational Statistics, 2018](#)). Such policies are reflective of public attitudes toward immigration in the United States that is revealed in local newspaper articles. The researchers used extant state-level data to identify the demographics, economic conditions, and political views about immigrants in the South Eastern United States as compared to the nation. They also used extant data from a higher education survey administered to 410 campus administrators.

They selected two 4-year campuses in different states in which to conduct case studies. They collected quantitative descriptive data about each campus, such as enrollment, race and ethnicity, amount of tuition, and percent of students receiving aid. For the qualitative part of the study, the researchers reviewed 215 newspaper articles published in newspapers in the two communities to collect data on how issues about undocumented students were reported. In one of the communities, a movement was started to pass a law to allow undocumented students to pay in-state tuition; the state's governor opposed the bill. The legislation was not passed and the universities were ordered to do an audit on all undocumented students and report on the tuition pricing. In the other case, a movement was started to allow an undocumented student to avoid deportation. The situation was widely reported and the student was allowed to stay because of her student status. However, the state legislator passed restrictive laws pertaining to admission and tuition pricing for undocumented students the next year.

The researchers included a stage of dissemination of findings for transformative purposes. They summarized the transformative effect as being the result of on-going engagement with campus practitioners:

Our assessment aided them in providing tangible patterns to draw on, and nuanced details about how the community privileges certain meanings that maintain oppressive realities. It was the integration of direct feedback from campus practitioners at all stages, from initiation of the research problem, to data collection, to analysis, and reanalysis that allowed us to shape the research process and the understanding of the issues that helped practitioners find a voice toward transformation (p. 431).

The practitioners reported that they had developed a sharper understanding of their complicit involvement in sustaining oppressive practices. The researchers continued their relationship with the campus collaborators through direct outreach and continued communication. They provided evidence to the campus practitioners and administrators about addressing power dynamics locally in order to be able to advocate for better practices in their institutions and professional organizations. Their collaborators developed an online repository of resources for campus leaders who wanted to advocate for the rights of immigrant and undocumented students. They have also produced policy briefs, trend reports, short factsheets, webinars, workshops, and syllabi to support critical examination of policies and avenues to support undocumented students.

Disabilities and deafness

The Secretary-General of the United Nations released a statement that strongly demands supportive inclusion of persons with disabilities and those who are Deaf in order to respect their right to receive an education ([UN General Assembly, 2020](#)). As noted earlier, students with disabilities and students who are Deaf are denied access to appropriate education in many parts of the world ([Wilson and Winiarczyk, 2014](#)). Deaf people are sometimes not provided with appropriate interpreters, a necessary service if they are to receive an education. Wilson and Winiarczyk conducted a transformative mixed methods study in Malaysia that included in-

depth interviews, focus groups, surveys, and naturally occurring observations. As both researchers are American, they employed the services of a Malaysian research facilitator who was fluent in Malaysian Sign Language and American Sign Language (ASL) (Winiarczyk is a Deaf researcher who uses ASL). They consulted as a team with the Malaysian Deaf Association and members of the Deaf Malaysian community on the appropriateness of the research objectives, questions, and data collection instruments and strategies to insure cultural responsiveness. They also used Participatory Rural Appraisal research techniques to facilitate group discussions. The resulting data revealed the reality of the Deaf Malaysians that was characterized by a lack of policy implementation to provide them with early childhood education, deaf education, and accessibility through supportive communication (e.g., trained interpreters). The Deaf community members used the data and the strategies they learned through participating in the research study to begin to advocate for education and accessibility in Malaysia.

The U.N. Secretary-General's statement (2020) identified the increasing use of online instruction due to the 2019–2020 Covid-19 pandemic as presenting additional challenges for persons with disabilities. Hyett et al. (2020) conducted a transformative mixed methods study to improve the quality of online instruction for students with disabilities at a mainstream school in Australia. The researchers identified one of the relevant contextual factors in this study as a major policy change in Australia in the form of the National Disability Insurance Scheme that provided funding to support people with significant disabilities in mainstream society.

The methods used included transcripts from six workshops, surveys (completed at the end of each workshop), document reviews, and individual interviews. The participants included teachers and their assistants, parents, and allied health professionals (occupational therapists and speech pathologists). The use of a codesign process to develop the intervention illustrates the use of a transformative lens in this study in that the researchers did not impose an intervention that they identified. Rather, the researchers developed relationships with educators, health professionals, and parents as equal partners in the research process. The knowledge that educators, health professionals, and parents gained from being in continuous and long-term contact with students with disabilities was valued and informed the development process. This knowledge was elicited by using a storytelling strategy during the workshops. The researchers emphasized "process, relationships, governance, and effective facilitation that prioritized power sharing and group dynamics" ((Greenhalgh et al., 2016) cited in Hyett et al., 2020, p. 2).

Representative educators, allied health professionals, and disability consultants (two parents of children with disabilities and two persons with disabilities) made up a governance council (advisory group) to guide the research team in decision making. The advisory group and the research team designed processes for engaging with these groups throughout the entire research process, from problem identification, understanding contextual issues, developing an intervention and processes for implementation, and collection of data throughout the study. The researchers chose not to include children with disabilities based on the rationale that they would not be the end users of the product. They further justified this decision based on the input they received from the persons with disabilities in the advisory group. The researchers specifically described how they addressed issues of power: "Strategies used to address power dynamics during this project were equal compensation, governance committee structure, group facilitation techniques, a self-report measure, and activities designed to promote equal participant contributions (p. 11)."

Transformations occurred for the participants during the codesign process in the form of increased understandings of the perspectives of those from the different groups, enhanced listening skills, and valuing of the codesign process. The online package for instruction was developed and approved through the workshop process, followed by a review by the advisory group. After making modifications based on input from these groups, the researchers posted the package to a website for external review by a wider professional community. After making additional revisions, the final online package was disseminated by posting to an open access website.

Additional examples of transformative mixed methods with populations who are Deaf or have a disability include: Hyett et al. (2020) used the transformative mixed methods approach to study strategies for improving inclusion of people with disabilities in educational programs in Australia. Munger and Mertens (2011) looked at ways to respectfully include adult people with cerebral palsy in decisions about their education in the United States. Wilson and Winiarczyk (2014) studied how to increase the educational supports for people who are Deaf in Malaysia, Chile and Argentina. Kutscher and Tuckwiller (2019) conducted a study to increase support for students with disabilities at the college level in the United States.

Indigenous populations

Indigenous scholars draw a distinction between the use of an Indigenous worldview and a transformative lens as frameworks for evaluation that share a common interest in positive transformation for those who experience discrimination and oppression (Chilisa, 2020; Chilisa and Mertens, 2021; Chouinard and Cram, 2020; Cram and Mertens, 2015, 2016; Mertens and Cram, 2016). An Indigenous perspective is rooted in the need to address decolonization as it relates to "sovereignty, land and resources, and freedom to live as Indigenous peoples" (p. 186) (LaFrance and Nichols, 2009, cited in Mertens and Cram, 2016). While both transformative and Indigenous researchers seek transformation to produce a more just society, Indigenous researchers see the importance of transformation in the form of repatriation of land and their relations to the land. This is a concept that is compatible with transformation for increased social, economic and environmental justice, but it is also quite specific to an Indigenous worldview. Both frameworks endorse the purpose of research as supporting change to increase the quality of lives for people who have experienced marginalization and discrimination. The Indigenous worldview adds to understanding the meaning of transformation by its focus on the ethics of developing relationships that are culturally respectful and that honor all those who came before, are here now, and will be here in the future. Framing research in this way raises this question: How would we design our research to incorporate this interpretation of ethics, develop ethical relationships, and ensure that the interventions that are implemented honor the past, present and future inhabitants? Chilisa (2020) and Chilisa and Mertens (2021) argue that the Indigenous framework needs to

be given priority in research with Indigenous communities. However, they also agree that the Indigenous framework can be combined with a transformative lens to create research that focuses on positive transformative change.

The HIV/AIDS epidemic has ravaged many communities, particularly in Southern Africa. Researchers from the University of Botswana and an American university partnered to address this problem through the development a program to prevent the spread of HIV/AIDS and other sexually transmitted diseases for adolescents in Botswana (Chilisa and Tsheko, 2014). The researchers framed their study from a postcolonial Indigenous perspective, deliberately chosen to avoid the dominance of Western approaches. They combined quantitative and qualitative data collection methods within a randomized controlled trial design. The research study began with forming relationships, including establishing three advisory groups: an external international expert research advisory group, a school and community professional and parent group, and a youth group. These groups discussed what it meant to decolonize the mind and research methodologies. The community advisory group was described as follows:

We formed community advisory boards to serve as community theorists that could bring to the research the cultural knowledge, values, and processes of knowledge creation that could serve to make the interventions we designed relevant and useful to the communities. Their main role was to decolonize the research process by bringing Botswana worldviews to the creation of knowledge to ensure that the research remained relevant and useful to them (p. 227).

Based on the advisory groups input, the researchers conducted preliminary data collections to understand the current status of HIV/AIDS and sexually transmitted diseases using both qualitative and quantitative methods. They used Indigenous qualitative methods of storytelling and examining local proverbs in local languages, as well as interviews, knowledge and attitudinal surveys, and extant data to obtain incidence data of disease disaggregated by age, gender, and tribe. The data revealed that the students had accurate knowledge of prevention and transmission of the diseases for the most part, however, they associated a sense of sadness and futility around the concept because they had lost so many loved ones and felt they might die too.

A second phase used Indigenous mixed methods to develop a culturally relevant survey to measure the beliefs, behaviors and attitudes toward risky behaviors. The quantitative survey was based on the qualitative data from interviews, but also on cultural knowledge that came through stories, myths, proverbs, songs, metaphors, and taboos. These methods resulted in the surfacing of perceptions of students about sex and sexuality that were not common in the literature, but were reflective of the cultural context. The community advisory board then reviewed the instrument to insure the acceptability of the content and language.

An intervention was then developed that reflected the need to address cultural context and emotional needs, rather than strictly focusing on knowledge of transmission and prevention (e.g., use of condoms, limiting number of partners). The intervention was situated in a school context and included 12 1 hour modules, and was led by trained youth. This intervention was then pilot tested with rich data collected via observations, interviews, and document reviews. Following revisions of the program based on the pilot data, the researchers employed a randomized experimental design to determine its effectiveness. The experimental group received the HIV/STI program while the control group received a health promotion intervention that addressed the risks of other diseases such as heart disease and diabetes. The researchers incorporated Indigenous mixed methods within the experimental framework, combining participatory action research with appreciative inquiry. "Indigenous conversational methods, namely, adolescents talking to their parents, talking circles and yarning, were used as data collection methods. One of the criticisms of participatory action research is that most of the approaches are problem focused aiming at discovering communities' unmet needs (p. 230)." The yarning activity was used on the last day to evaluate participants' views on the effectiveness of the intervention. It consists of a facilitator who holds a ball of yarn and sharing what they have learned; the ball is then thrown to the next person until each person has a chance to talk. The end result is a visual picture of a web of connections that shows how everyone is connected to everyone else. The participants reported being transformed by building relationships, developing positive identities, and creating images of hope and a brighter future. The curriculum was then shared more widely in the Botswana school system and the results were shared with policy makers to inform future educational policies. The importance of addressing not just the acquisition of knowledge but also the need to build confidence in a brighter future is key to making healthy behavioral choices.

Implications for teacher research

The paradigm shift in the research world toward a framework that is transformative and explicitly addresses issues of equity has implications for the preparation of teachers and for teacher research. Teachers in the United States are primarily White, hearing, CIS-gendered, able-bodied, middleclass women. This creates a challenge for the majority of the teachers in the workforce to understand the experiences of people of color and people with disabilities, those who are Deaf, members of the LGBTQ+ community, or students whose backgrounds and living conditions are not familiar to the teachers. Accrediting agencies are giving greater attention to issues of diversity and reducing disparities in educational achievement on the basis of race, gender, and disability (Beck, 2020). The goal of achievement of those impoverished and marginalized is not only an issue in the United States, many countries are exploring how to address educational disparities. It is one of the Sustainable Development Goals endorsed by the United Nations for achievement by 2035 (Chilisa and Mertens, 2021).

Beck (2020) recommends the use of a transformative lens in preparation and research as a mechanism for bridging the gap, especially in communities with a majority population that is Black, Latinx, or Indigenous. Her rationale is presented in the following quotation:

... transformative mixed methods research (Mertens, 2010) has the explicit purpose of responding to societal inequities, engaging culturally diverse groups, and advancing social justice. Mertens (2010) noted that this model “supports the use of a cyclical model in which community members are brought into the research process from the beginning and throughout the process in a variety of roles” (p. 472). Thus, this model privileges a variety of members in the research process ... Cultural competence is critical for researchers utilizing transformative mixed methods. This design begins with a qualitative component to learn about the community being studied and to develop trusting relationships between stakeholders. The focus in this design is on producing change.

Beck (2020, p. 385).

A transformative mixed methods research agenda in teacher education provides a framework for educational researchers to work with schools and community members to prepare teachers who are equipped to address the challenges of discrimination and oppression. Researchers can thus demonstrate the value they place on knowledge based on lived experience that is sometimes missing in research that is designed based on scholarly literature alone. They can design studies that address differences in power in the typical hierarchical structure of schools and universities. Development of interventions can be based on theory and practice vetted through the eyes of those with lived experience. This provides an opportunity for schools to engage in continuous improvement through the cyclical collection of data, review and interpretation, and revisions based on earlier stages of research.

Conclusions

Educators experience the diversity of students in their institutions and recognize that different approaches are needed in order to address disparities in achievement. The transformative lens provides insights into the basis for disparities through engagement with the full range of people impacted by educational services. It brings attention to the need to be inclusive in building relationships so that the knowledge from researchers, school personnel, students, parents and other community members can be used to inform understandings of the nature of the problem and of interventions that are rooted in the culture and context of the community. Transformative mixed methods research incorporates multiple sources of data collected through multiple culturally responsive strategies with the goal of using the process and the findings to increase social justice.

Introduction

Integration is central to any definition of mixed methods research. It is what distinguishes it from multimethod research where data from different sources are analyzed and sometime linked but not brought together in a meaningful way that impacts analytical insight. Integration involves strategies that allow for purposeful interaction between qualitative and quantitative data and/or analytical procedures. This chapter addresses both “what” and “how” questions about integration. It introduces different viewpoints about what is meant by the word “integration” as compared to “mixing.” The discussion about design and philosophical assumptions that facilitate its meaningful uses, and the identification of four integrative analytical strategies addresses the question of how integration occurs.

Both mixed methods and multimethod research share the motivation to more fully understand complex social phenomenon, such as about immigration or domestic and international terrorism in real-world contexts, and that this is best accomplished by accessing multiple different sources and types of data. Researchers using a multi-method approach often combine multiple qualitative approaches or multiple quantitative approaches (Plano Clark and Ivankova, 2016). Mixing is not achieved just at the technical level of by collecting both qualitative and quantitative data. Mixing can occur at multiple levels including by partnering more than one methodology, like mixed methods and case study, participatory action research, or grounded theory. It can also involve engaging different disciplinary perspectives or theoretical perspectives (Greene, 2015). “The possibility of mixing at *multiple levels* (emphasis hers) is integral to the characteristics of mixed method approach,” Jennifer Greene, an influential opinion leader in mixed methods, observed (2015, p. 607).

Fully integrated mixed method research

The logic of integration is most fully realized in a fully integrated mixed methods design (Fetters and Molina Azorin, 2017, 2019). Qualitative and quantitative strands of a research study are brought together at many points during the research process in a fully integrated mixed methods design. This is referred to as an embedded approach to integration (Fetters and Molina Azorin, 2017). Research done with a fully integrated approach are often difficult to classify with the conventional terminology used in mixed methods to describe the research design.

A fully integrated approach to mixed methods, for example, might be launched during the design phase with a research question that requires both qualitative and quantitative data to address. The same logic could be extended to sampling and could occur, for example, when both qualitative and quantitative data are used to identify a sample of participants. Similarly, both qualitative and quantitative data can be collected simultaneously, such as when a researcher engages a participant in co-constructing a map of his or her neighborhood. There are multiple strategies to integrate during analysis, including through joint displays that combine findings from quantitative and qualitative analytical procedures. At the final stage of the research process before reporting begins, findings from the different analytical techniques can be integrated to construct a figure that reflects a composite, holistic understanding of the phenomenon.

Distinguishing between mixing and integration

Some methodologists with expertise in mixed methods maintain that more attention needs to be devoted to distinguishing between the terms “mixing” and “integration” (e.g., [Fetters and Molina Azorin, 2017](#)). [Fetters and Molina Azorin \(2017\)](#) suggest that the term integration is often used too narrowly to refer to either merging or combining data. These authors suggest that the key to advancing the understanding of the term “integration” is to apply it to a fully integrated approach where qualitative and quantitative approaches interact in meaningful ways during all phases of the research process.

The word “integration” carries different meaning in the context of mixed method research than the word “mixing.” Integration refers to the type of purposeful engagement of different types of data or analytical procedures in ways that have an effect on the analytic density or conceptual multi-dimensionality. Analytic density refers to the potential to build the type of multi-dimensional conceptual understanding of social phenomenon that is essential to the iterative process of building knowledge in a scientific way ([Fielding, 2012](#)). No one approach or method is subordinated in this type of approach to mixed methods. The product is synergistic. That means that the outcome goes beyond what was extracted from the separate parts. In this case, it is much more difficult to disaggregate the findings during reporting into separate publications devoted to the qualitative findings and the quantitative results.

Estimates of the frequency of meaningful integration in mixed method designs

The potential to integrate findings from different analytical procedures in meaningful ways was rarely optimized when mixed methods first emerged as a distinct methodology. Some of this may be attributed to the social mindset in the 1980s during the so-called “paradigm wars” ([Howe, 1988](#)) that raged as qualitative approaches were beginning to gain legitimacy. [O’Cathain et al. \(2007\)](#) provided evidence that integration was not an every-day occurrence in mixed method research during the early days of mixed methods. Their systematic application of a rubric that tabulated at what phase in the research process mixing occurred, revealed the surprising finding that only a small percentage of studies (16% of 49) conceived as mixed methods, resulted in publications that provided evidence that the qualitative and quantitative strands were integrated. The practice of publishing qualitative and quantitative findings in separate articles complicates attempts to get a full picture of how integration occurs in a mixed methods study ([Archibald et al., 2015](#)).

It is challenging to reach an accurate estimate of how frequently integration occurs in mixed method publications. Drawing conclusions about integration from a single article is more feasible in a straightforward, two-phase design than it is in a more complex, multi-phase design where team members produce a much larger body of work. Some types of integration, such as how a theoretical framework was used as a guide to integration across research phases, cannot be gauged accurately at the level of a single study ([Maxwell et al., 2015](#)). Recognizing the complexity of the ways mixed methods are used in practice, particularly in a randomized control trial (RCT), [Creamer et al. \(2020\)](#) suggest that reaching a judgment about research quality in a multi-phase mixed method research project is better done by weighing more than a single article.

Navigating the aftershock of the paradigm wars

Discussion about philosophical paradigms has had a prominent role in the discourse about mixed methods since its inception as a distinct research methodology. The influence of postpositivist perspective in the mixed method discourse ([Denzin, 2010](#)) may account for the assumption that it is preferable to keep qualitative and quantitative analysis separate. The postpositivist paradigm dominated social science thought in the 1980s and 1990 when qualitative and quantitative research coexisted but as separate and competing paradigms ([Johnson et al., 2007](#)). The expression, incompatibility thesis, refers to the epistemological position that qualitative and quantitative data and analytical procedures should not be integrated prior to the final stage of interpretation because they emanate from antithetical philosophical positions about the nature of knowledge and legitimate ways of constructing it.

The idea that qualitative and quantitative approaches are incompatible paradigmatically still holds sway in some academic domains, like psychology and the health sciences, where experimental research is the gold standard. One way that this viewpoint is mirrored in the design of a mixed methods study is by keeping the qualitative and quantitative strands separate until they are brought together during the process of drawing conclusions. This further impacts research designs because it means that there are separate quantitative and qualitative research questions. The incompatibility thesis extends to those who hold fast to the idea that qualitative and quantitative data cannot be integrated because they reflect, as nursing educator [Morse \(2010\)](#) asserts, different levels of abstraction or interpretation.

A person writing about integration in mixed methods research for decades, Pat Bazeley, takes a strong position about designs that fail to engage qualitative and quantitative data in meaningful ways. “The strategy that is most destructive of coherent integration,” Bazeley writes, “is to work through a complex analysis of each of the separate sources or data types available *before* considering how they might be integrated” ([Bazeley, 2018](#), p. 283, emphasis hers). She joins others in challenging the incompatibility thesis by pointing out the similarities between research approaches with an empirical drive. Integration throughout the research cycle is paradigmatically supportable by the argument from constructivism that all research has a subjective, interpretive component.

Philosophical grounding that supports an interactive and iterative approach to integration

Mixed method approaches have been adapted as a research approach by investigators operating from paradigms with diverse epistemological and ontological assumptions about the nature of reality, what constitutes research, whether values play a legitimate role, and the types of tools that are needed to conduct it. Some writing about mixed methods affiliate with the lens of dialectical pluralism as a guide for investigators committed to the exploration of diverse perspectives (e.g., [Johnson, 2012](#)). The contribution of dissonance, paradox, incongruities, and gaps and silences that is part of the dialectical perspective is a defining characteristic of what Jennifer Greene famously referred to as a “mixed method way of thinking” (2007, p. 20). Unexpected findings can offer a powerful incentive to integrate findings from different sources of data in search of an explanation.

Procedures that promote integration

A number of analytical strategies promote meaningful integration, including by pairing with other methodologies, like grounded theory ([Creamer, 2021](#)). These include (1) framing a research problem in a multi-dimensional way, (2) integrating through case-based analysis, (3) integrating through visual displays, including joint displays, and (4) integrating through a methodological or conceptual framework.

Table 1 identifies four strategies for mixed method analysis and provides a definition for each.

Framing a research problem in a multi-dimensional way

Integration can be enhanced by conceiving social problems in a multi-dimensional way and by conceptualizing core constructs as nested within micro, meso, and macro levels of social structure. Micro level constructs relate to individuals’ beliefs, attitudes, interactions, motivations, and aptitudes. Meso level constructs could involve a community or organization. Macro level constructs reflect how individual perceptions or actions might more fully be understood within the broader context of the social and political environment. Using only one source of data necessarily represents a partial picture of a phenomenon. It is just one facet or dimension of a wider phenomenon.

Bi-dimensional thinking might pose a research question that considers the relationship between two variables. This could be the case, for example, in the exploration of the link between any type of intervention and anticipated outcomes. A more multi-layered, and thus theoretical, perspective is introduced by considering contextual factors or more local conditions that might mitigate the impact of the intervention or the flow in a temporal process.

Framing a research problem in a multi-dimensional way facilitates what could be called theoretical integration by creating an opportunity to link qualitatively and quantitatively derived constructs. In this context, connecting or integrating evidence occurs during analysis. It is not a mechanical or procedural matter, but a theoretical one that is generally accomplished with an eye to the literature and other relevant theoretical frameworks.

The purpose served is to gain a more holistic picture by exploring different aspects of the same phenomenon. This is referred to as complementarity ([Greene et al., 1989](#)). It is often the case in research involving interventions that quantitative data is used to measure outcomes and qualitative data to identify links between variables or to pinpoint an underlying social process ([Johnson and Schoonenboom, 2015](#)). There is nothing that prohibits that both qualitative and quantitative data could be used to corroborate the same construct or the links between them ([Bussing et al., 2012](#)).

Integrating through case-based analysis

Perhaps more so than any other procedure that I have identified, case-based analysis can provide the basis for integration at the multiple levels of the analysis that [Greene \(2015\)](#) referred to. In case-based analysis, narratives or visual displays are constructed that integrate data from multiple sources about the same unit of analysis. An individual, group, classroom, or location are examples

Table 1 Examples of mixed method analytical strategies that promote integration.

<i>Mixed analytical strategy</i>	<i>Definition</i>
Framing a research question	A research question that links qualitative and quantitative constructs to create a more multi-layered understanding of a social phenomenon.
Case-based analysis	Merges qualitative and quantitative data through the construction of a narrative or visual about each case for purposes of conducting a cross-case comparison.
Joint displays & other types of displays	Integrates qualitative and quantitative data or findings in a table, figure, matrix, or graph.
Integrated theoretical framework	Embeds multi-dimensionality in a figure or table by integrating qualitative findings and quantitative results, most often to offer an explanation for a social process.

of what can provide the unit of analysis for a case. The purpose of the construction of cases is formative in that they are used for the basis of further analysis through a cross-case comparison.

Case-based analysis create opportunities for integration at multiple levels. This includes integration of data from multiple sources into case narratives or profiles. It extends to integration that occurs through conducting cross-case comparisons with an abductive logic that occurs when preliminary inferences are integrated to generate tentative hypotheses which are subsequently explored further through an inductive or deductive logic. It also includes integration that occurs when an eye is kept on how emerging findings fit and do not fit with the literature. Internal validity is extended by the generation and testing of multiple, and on occasion, contradictory explanation that help to unsettle preconceptions, strengthen grounding, and distract from foreclosing prematurely on an obvious explanations.

An additional way that integration can occur through case-based analysis in a mixed method study is in the use of cases constructed with multiple sources of data to test an existing theory or to elaborate it. For example, support can be calibrated for the extent that each case supports different theoretical propositions. An investigator might turn to case profiles or memos that integrate data from multiple sources to explore if how an emerging theory might need to be refined to account for exceptions.

Integrating through joint displays

A figure or table that integrates qualitative and quantitative data is an integrative strategy that has probably received more attention than any other strategy in the mixed methods literature (Plano Clark and Sanders, 2015). A joint display is a table or figure that encourages integrative thinking during analysis by arraying and sometimes linking qualitative and quantitative data about the same constructs, research question, or themes.

A visual display that integrates qualitative and quantitative data can serve multiple roles in both developing and supporting findings. Their role is a formative one when the juxtaposition of findings from different sources of data generates new insight about a pattern or association. This can lead to a new round of theoretical propositions or themes that are pursued through further analysis and/or data collection even when the data at first seems contradictory.

An additional purpose for an integrative visual display is triangulation. This is when a table or figure provides enough data to support the credibility of conclusions. A well-crafted visual display can warrant a conclusion by showing the empirical support for it (Fetters and Guetterman, 2021). This type of visual display can document the quantitative and qualitative support for a hypotheses, theme, or construct. Its purpose is related to warranting because it shows the extent that key conclusions, inferences, themes, and/or hypotheses are corroborated by analysis from more than one source of data. This type of table generally reveals areas where findings triangulate, as well as areas where the data are not in accord (Creamer, 2021).

Integrating through a methodological or conceptual framework

It is an expectation in many academic disciplines in the human and behavioral sciences, such as psychology, that an investigator ground the design of a research study in a theoretical framework whose reliability has been documented. This is less so the case in applied fields like education and nursing. It is not uncommon for investigators in applied fields to launch a project with a conceptual framework produced from literature. Theoretical integration can be achieved through conceptual framework that combines components of more than one theoretical perspective. Over the life of a research project, a conceptual framework is generally subject to on-going refinement and revisions.

A conceptual framework can facilitate the integration of data and findings from multiple sources in a number of ways. One of its functions during the design of study is to single out a tentative set of core constructs that can be used initially to select appropriate instruments or to structure data collection instruments that are original to the project. A conceptual framework can provide a preliminary shell of a coding scheme to be applied qualitatively. A third way a conceptual framework is related to integration is to provide a preliminary explanation for incongruities that emerge between findings from different sources of data. When applied too prescriptively or used in a way that narrows the range of explanations considered, a conceptual framework can inhibit integration.

Other design features that promote integration

The design of a mixed method study is often represented in a figure that maps the sequence and timing of key phases of a research project. In addition to the analytical procedures described above, several features of design can promote integration in a mixed methods study. Most of these influence decisions that are made about the research design during the planning phase.

1. There is at least one research question that requires both qualitative and quantitative data to answer.
2. Both qualitative, quantitative, and sometimes visual or auditory, data are collected about core constructs.
3. Qualitative and quantitative data are linked in a single database (Bazeley, 2018; Creswell and Plano Clark, 2011).
4. Sampling is embedded. This means that there is both qualitative and quantitative data about the participants or a sub-set of the participants.
5. Comparable resources and expertise are invested to all of the methods.
6. If it is a team-based project, there is overlap in the methodological and content-oriented expertise that allows more than one person to play a part in analyzing the data from different strands or phases of the study.

It is often the case that selecting the most appropriate terminology to describe the design of a mixed methods study cannot be fully realized until the research is well underway.

Characterizing mixed priority research

It has been the practice in mixed methods reporting to label research as reflecting one of three priorities: quantitative, qualitative, or equal priority. Iterative and integrated mixed methods designs are often characterized as reflecting equal priority because neither method is subordinated or treated in a perfunctory way. The term “equal priority” is not entirely satisfactory in situations where the conclusions, like what might be presented in a composite theoretical model, communicates a situation where the outcomes of a project cannot be directly traced to a single method.

The expression mixed methods priority is a way to communicate that findings from each method contributed in a meaningful way to generating a cohesive and coherent explanation (Creamer, 2018). Mixed priority communicates that key findings emerged from a dialectical interplay between data and methods. It provides a shorthand to communicate that the results of a project were synergistic.

Concluding thoughts

Mixed methods is a dynamic and a rapidly evolving methodological approach that is embraced by diverse disciplinary communities and implemented in settings across the world. It is characterized by the remarkable variety of the ways it has been adapted to understand complex phenomena in diverse, multi-disciplinary settings. The topic of integration is at the center of contemporary scholarship about mixed methods where there is growing attention to its potential to be embedded at many points in the research process (Creamer, 2018; Fetter and Molina Azorin, 2019), including by mixing methods, perspectives, and theoretical and paradigmatic orientations.

The type of mixing used in a mixed method study and whether it occurs in one or more places during the research process has implications for how research methods and findings are reported and for how teams conduct their work. It is recommended that manuscripts include a section devoted to integration in the portions of a manuscript that describe the research procedures and the results. It is helpful, as well, to specify when mixing occurred in a flowchart or procedural diagram designed to documents how data collection and analysis occurred.

Research conducted with a distinct qualitative phase and a distinct quantitative one, accommodates settings where collaborators have infrequent interaction, work relatively independently because there is little overlap in expertise, and have responsibility for deliverables at different points in time. The more interactive and iterative approaches I have highlighted accommodate an applied purpose and are embedded in real-world agencies, like schools, hospitals, or community agencies that are in a constant state of flux. Some researchers turn to mixed methods when findings from different sources of data do not cohere in expected ways. An interactive approach is suited to settings where there is an opportunity for frequent and on-going interaction among collaborators. This is likely to be where there is enough overlap in both methodological and topic-related expertise, that multiple investigators contribute to the analysis. There is a high level of involvement with participants across many phases of the research project in participatory action research (Ivankova, 2015). It is not possible for a single approach to mixed methods to be suitable to all research questions and conditions.

Overview of cultural studies in education

Cultural studies in education, considered an institutionalized discipline, is a plural field of enquiry that “draws from whatever fields are necessary to produce knowledge required for a particular project” (Grossberg et al., 1992, p. 2). The evolution of cultural studies in education started when British cultural studies first made its entry into the discipline of education in the United States during the late 1970s–1980s (Giroux and Shannon, 2013). As noted by Hytten (1999), educators in the discipline of cultural studies focus on two main areas, the traditions of pedagogy guided by critical theory (“critical theory challenges the status quo and strive for a balance and democratic society”, Asghar, 2013, p. 3123) and ethnic and diversity studies. Other dimensions of cultural studies in education include multiculturalism, interculturalism and cross-culturalism. Multi-cultural education involves recognizing and respecting diverse cultures and identities within the school system so that education can be more equitable, harmonious and fair for all (Gay, 1997; Bennett, 2015) whereas intercultural education emphasizes interpersonal relationships among different cultures (Chiriac and Panciuc, 2015). In other words, there is mutual exchange or interactions of ideas and cultural norms that result in deeper relationships in a multicultural society. Crosscultural studies involve persons from different ethnic groups and countries. Crosscultural studies in education allow for understanding human behavior through the comparison of different perspectives to enable the expansion of knowledge of a dominant culture (Papayiannis and Anastassiou–Hadjicharalambous, 2011).

Additionally, research into multiculturalism, interculturalism and cross cultural education can be guided by different paradigmatic stances, such as pragmatism, transformative and critical theory. Paradigmatic stances “are systems of beliefs and practices that influence how researchers select both the questions they study and methods they use to study them” (Morgan, 2007, p. 9). Pragmatism ascribes to multiple realities which enables research in cultural studies in education to be richer and comprehensive because of an interchange of different views on life, which may also productively stimulate new ways of thinking while conserving valuable aspects of tradition (Shannon–Baker, 2016; Shusterman, 2010). Critical educators challenge the dominant culture “to rethink notions of difference, privilege, and power. They have challenged the implicit social norms of those with power and called for us to uncover (so as to alter) the operations of the culture of power” (Hytten, 1999, p. 531). Transformative paradigm sensitizes researchers in education in both methodological and philosophical ways that recognize the construction of multiple realities. These realities are imbued by diverse socio-cultural impositions and human rights issues in those realities throughout the research process (Hunt–Anderson, 2021). The distinguishing feature of critical theory from transformative is that critical theory increases awareness of the differentials within power structures, while transformative theory leads to a change in beliefs and perspectives that ultimately change behaviors and activities of individuals (Wang et al., 2019).

Due to the variety of paradigms that are available to guide the cultural studies researcher across diverse contexts, we agree with Nelson et al. (1992) that there is no distinct methodology or set guidelines in how or what questions and answers need to be explored in educational contexts. A cultural study in education researcher may find that mixed methods research provides a range of philosophical and methodological approaches that are useful, this is because the approach can be framed from traditional to more critical lenses. Research in cultural studies in education can be richer in understanding and improving relationships among students of different cultures within education institutions, which may also productively stimulate new ways of thinking and relating while conserving core attributes of the multiple cultures represented in an educational context.

Mixed methods research (MMR) represents an approach with the potential to explore cultural issues or phenomena such as the nexus of context and education, capturing the uniqueness of educational issues within cultures (Bartholomew and Brown, 2012). Cultural phenomena are unpredictable and are characterized by combinations of multiple, and non-linear patterns and directions (Poth, 2018). While acknowledging that the definition of MMR has evolved over the years, Creswell and Plano Clark (2018) emphasize that MMR involves a process (not necessarily in the same order) of using specific mixed methods designs for a study, developing a philosophical and theoretical framework for the study, collecting and analyzing both quantitative and qualitative forms of data, and integrating these data forms and their results. The main purpose of integrating is to enhance understanding of a phenomenon or issue under investigation, and to this end, there is a growing interest among researchers in using MMR approaches in cultural studies in education.

In this chapter, we offer insights on how MMR designs are utilized in different domains of cultural studies in education—multicultural, intercultural, and cross-cultural, which enhanced greater understanding of the phenomenon being studied and the possibility of achieving positive socio-cultural change in the educational context. More specifically we discuss how integration of qualitative and quantitative approaches in a single study facilitates and enhances the research process in understanding issues in education within cultural contexts. In the chapter, we also examine the role of pragmatism as a fundamental MMR philosophical approach. The chapter also includes examples to provide insights of how researchers utilized and benefitted from using MMR designs in three domains of cultural studies in education (multicultural, intercultural, and cross cultural).

Cultural studies in education and mixed methods research

Discussions specific to methods in cultural studies in education have been largely under-described (Pickering, 2008). As such, methods that place emphases on understandings of the issues of power are relevant and appropriate for cultural studies researchers. Cultural studies in education are leaning toward more empirical forms of research as researchers seek evidence to analyze and interpret cultural theories and frameworks, pedagogies, and praxis (Pickering, 2008). There is a need to expand the debate in education where the field of cultural studies offer an opportunity to build on existing research designs and models by examining texts, stories, images and how one comes to understand the world they live in. Such understandings are facilitated by our theoretical underpinnings. For example, critical theoretical frameworks play a pivotal role in understanding cultural studies in education to uncover and discover issues that often challenge existing norms (Trifonas, 2020).

Several approaches and methods can be adopted in cultural studies in education for inquiry such as case study (Guetterman and Mitchell, 2016) or participatory action research (Goldberg, 2020) that utilizes deductive or inductive approaches or a combination of both, which is termed abductive. According to Mitchell (2018), abduction enables rigorous search of the data, testing ideas, checking and trying to understand differences in interview responses under various circumstances, in short, what occurs in practice and the reasons why. Although cultural studies in education has traditionally followed the mode of enquiry of an anthropologist seeking to develop an in-depth understanding of a culture through participation, mixed methods research allows a researcher to use abductive logic in their research and to work toward the “radical middle” (Onwuegbuzie, 2012).

Philosophical foundations for mixed methods cultural studies in education

Mixed methods researchers are encouraged to be cognizant of the philosophical assumptions that guide their work (Creamer, 2018a; Creswell and Plano Clark, 2018; Johnson and Onwuegbuzie, 2004; Shannon-Baker, 2016). The need for researchers to make their philosophical assumptions explicit is described by Creamer (2018a) as philosophical transparency, that is, when the authors discuss their work’s philosophical framework in details. A paradigm is often described as the researcher’s philosophical assumptions or worldview about the nature of reality and the researcher’s role in constructing what is agreed upon by a community of scholars (Creamer, 2018a,b). As mentioned earlier, pragmatism is most commonly associated with MMR (Creamer, 2018a,b). Pragmatism prefers action to philosophizing and “takes an explicitly value-oriented approach to research that is derived from cultural values” (Johnson and Onwuegbuzie, 2004, p. 18).

As we reviewed the literature for scholarly articles on cultural studies in education that utilized MMR approaches, we found only one of forty-three articles that identified and discussed a research paradigm in their study. Ungar and Liebenberg (2011), identified and discussed a research paradigm to frame their study; they declared their research paradigm as transformative. Our finding which is similar to that of Alise and Teddlie (2010) who, in their investigation of six hundred research articles, found only one that mentioned an underlying philosophical research assumption. This indicates that researchers have neglected to state their worldviews, thus, according to Creamer (2018a,b) lack philosophical transparency. Regardless of the disciplinary background, mixed methods researchers should at least understand the philosophical assumptions that underpin MMR and how these assumptions can have an impact on the way the study is designed and conducted. Throughout this chapter, we emphasize the importance of encouraging mixed methods researchers to be more explicit about their paradigm in their reporting of MMR investigations. As Shannon-Baker (2016) explains, “paradigms can help frame one’s approach to a research problem and offer suggestions for how to address it given certain beliefs about the world” (p. 321). Hence, the inclusion of the research paradigm will help to shape and authenticate an MMR study.

Mixed methods research and integration

In addition to exploring the paradigmatic underpinnings of MMR, it is important to discuss its defining attribute—integration. Integration is the point in the research process where the quantitative and qualitative research approaches interface (Creswell and Plano Clark, 2018). It is this attribute that distinguishes MMR from multi-methods research. It is recommended therefore, that mixed methods researchers illustrate how and where integration occurs in the research procedures (Creswell, 2022).

Although the interfacing of quantitative and qualitative research approaches may be written into a study's title, purpose statement and research questions (Creswell and Plano Clark, 2018), there are four basic methods of linking quantitative and qualitative datasets in mixed methods research: connecting, building, merging, and embedding (Creswell and Plano Clark, 2018; Fetters et al., 2013). Connecting is linking one database to the other through sampling. Usually, quantitative data are collected and analyzed in the first phase. Then, the results from the quantitative analysis with inclusion criteria allow the researcher to select a subgroup of participants for the qualitative phase (to collect data using techniques such as interviews, focus groups, observation, etc.). The researcher's intent for the qualitative phase is to expand or elaborate on the quantitative results. Building occurs when the qualitative data are collected and analyzed in the first phase. Then, the information garnered from the qualitative is used to develop an instrument, an intervention, or identify new quantitative variables. For integration through merging, the qualitative and quantitative data are collected and analyzed separately and then, the results from both stages are linked or merged to compare and contrast, in other words, to identify convergences and divergences (Creswell, 2022).

Integration in MMR is a purposeful interdependence between the methods within the two research approaches (quantitative and qualitative) (Creamer, 2018a). Creamer makes the distinction between a component (multi-methods) design and an integrated design. In the component design, integration of findings occurs only in the conclusions, while an integrated MMR design, according to Creamer (2018a) is, "one where there is an ongoing interaction between the data and/or methods at many points in the research process" (p. 2). This is a synergy between two research approaches (quantitative and qualitative) that can take place in the conceptual and methodological frameworks, presentation of results and inferential stages/sections of the research process; these sections are "brought together into a coherent whole" (Creamer, 2020, p. 2).

Illustrative examples of cultural studies in education and MMR

Given the above discussion, we offer an examination of published research in different cultural contexts to understand the benefits of using MMR designs in cultural studies in education. Thus, we present three examples from three cultural domains: multicultural, inter-cultural, and cross-cultural in a higher educational context, that illustrate how mixed methods research has been utilized in cultural studies in education. In the first example, we review a Finnish study by Acquah and Commins' (2013) who evaluated a multi-cultural course for exchange students. The second example is inter-cultural by Tajima (2019, 2020) who conducted a study on Japanese students in a short-term study-abroad program in Canada. The third example by Ungar and Liebenberg (2011) is based in Canada where they conducted a 3-year, cross-cultural pilot study of child and youth resilience across fourteen communities within eleven countries.

A multicultural study in education using MMR

Multicultural education provides a space for dialog and understanding of diverse cultural groups and their inter- and intra-relationships. Groups with the most power learn to listen to and collaborate with those with less power, particularly regarding education issues. It allows for the interrogation of power in defining education's purposes and processes in a diverse and unequal world (Gay, 1997; Bennett, 2015).

Acquah and Commins' (2013) study examined "pre-service teachers' knowledge of issues related to multiculturalism and diversity before and after taking a multicultural education course" (p. 445). The researchers used an MMR approach but did not explicitly provide a rationale nor did they declare the type of MMR design which would have provided some indication of the rationale. It was only in the reporting of the findings that it became evident that the intent for using an MMR was to ensure reliability through triangulation and to obtain a more expanded understanding of the quantitative results through the qualitative data analysis.

There were two research questions that they used to guide their study:

- (1) How culturally aware are pre-service teachers at the point of entry a multicultural education course and at the point of completion? and (2) Do pre-service teachers believe they know cultural diversity and teach minority students after taking a multicultural education course? (p. 4).

Data were collected from thirty-eight student teachers, thirty-five females and three males, registered for a multicultural education course at an urban university in Southwestern Finland during an autumn semester of an academic year. These students were from seventeen countries both within and outside of Europe, Finland, Cameroon, Nigeria, Pakistan, Greece, Iran, Ireland, Korea, Hungary, Romania, China, Germany Austria, Spain, Serbia, Taiwan and Poland. Data were collected using a survey questionnaire, pre- and post-test journals, reflections, focus groups, and a final evaluation. Participants were guaranteed anonymity and confidentiality.

Students were asked to keep a learning journal. These facilitated students' reflection "on their learning from each reading, lecture, and seminar, how they challenged their prior beliefs or reinforced them and how the new learning was going to influence their future practice as teachers" (Acquah and Commins, 2013, p. 450). The final evaluation involved students writing comments on the most and least helpful aspects of the course. The survey instrument required students to rate themselves on the items using a five-point scale for the first three items and 3-point scale for the last item.

In the article, quantitative results were first presented. The paired sample *t*-test result showed that preservice teachers were more knowledgeable about multicultural concepts at the end of the course. This was followed by the qualitative data that expanded the quantitative results. The qualitative details gave insights concerning how the course improved the student teachers' understanding of multicultural education and assisted the researchers in identifying the various aspects of the course that resulted in an improved understanding of multicultural education. This connection between the quantitative and qualitative datasets was not presented graphically. However, the researchers discussed the quantitative results and used several exemplary excerpts to substantiate the qualitative assertions concerning the improvements of the students' understanding of multicultural education. There was also some indication of a link between both datasets in their conclusions. We conclude from this article, that integration occurred at two obvious points which therefore validates the study as an MMR if we are to follow Creamer's (2018a) definition.

We also noted that these authors did not mention or discuss a research paradigm. As mentioned earlier, a research paradigm clarifies the worldview and assumptions that guide the research methods and strategies. In other words, the paradigm helps the audience to understand the underlining reasons for the methodological decisions made while conducting the study. Despite the lack of declaration, an MMR expert could infer that pragmatism was the underlining paradigm as the researcher appeared to be open minded to mixing different research approaches within the study (Shusterman, 2010). An alternate paradigm that could have guided the methodological decisions is critical theory since multiculturalism is concerned with alternate realities to that of the dominant culture a society. Critical theorists challenge the dominant culture to rethink notions of different privilege and power (Hytten, 1999, p. 531). Mixed methods researchers are being encouraged by international experts to be explicit about their research paradigm which can help to guide novice researchers in their MMR endeavors. While we must keep in mind the word count constraints of journal articles, at the very least, a paradigm(s) should be articulated concisely.

In terms of content, we felt that the information garnered from the MMR findings gave a more comprehensive understanding of the impact of multicultural education on the course participants. The qualitative findings extended the breadth of the quantitative results. For example, before engaging with the course materials, the students were required to write their definitions of key terms which would be covered in the course. In addition, the students indicated that they desired to acquire knowledge and skills to teach diverse students and broaden their understanding of multiculturalism. The participating students also wanted to increase their capacity to help children from minority groups integrate into school. At the end of the course, students responded to a survey indicating the extent to which the course goals were accomplished. Also, they were required to update their definitions of the key concepts in the course. Their definitions of the key concepts before and after the course were used to add validity to their responses on the survey and show how the students reframed their understanding of core concepts of multicultural based on the course. Through these data, the researchers were able to ascertain how the course content influenced the students' knowledge and skills. The information was also used to identify students (they were the minority) who did not benefit as the facilitators hoped. Also, the authors noted that a small number of students did not gain as much and still had "vague ideas about key terms." This was garnered from comparing both definitions of key concepts before and after the course. Therefore, this MMR study was equipped with multiple research tools that facilitated inclusiveness and unfolded different layers of students' understanding of the various concepts in multi-cultural education. As such, the combined results from the different layers provided a more comprehensive understanding of multi-cultural education which is the basis for conducting an MMR study.

An intercultural study in education using MMR

Intercultural education is the process through which "people become aware of other ways of thinking, living or behaving and how they perceive their experiences with others" (Merino and Avello, 2014, p. 285). Given racial and economic inequalities in educational outcomes, leaving no child behind must assume that intercultural sensitivity and competence are critical components to combating racism and discrimination in schools (Darling-Hammond, 2010). Intercultural competence is defined as "the ability to interact effectively with people of cultures other than one's own" (Byram, 2000, p. 297). The study by Tajima (2019, 2020) is an example of how MMR was used in exploring intercultural awareness in education.

Tajima published her study in two parts (2019 and 2020) describing her utilization of a mixed methods case study research design (MM + CSR) to investigate a study abroad (SA) program. She focused on twenty-nine Japanese students from two universities who took part in a four-week exchange program in British Columbia and Alberta, Canada. The program was organized through the university and earned the participants credits. They were females between 18 and 22 years and had limited opportunities to use English language outside the classroom. The SA program took place between semesters. The host university organized cultural activities and tours for participating students.

According to Tajima (2019), the purpose of the overall study was "to provide a critical understanding of the ... interconnection of Second Language (L2) proficiency, affective factors and language use in different SA contexts" (p. 515). She explored constructs of L2 learning, willingness to communicate (WTC), motivation, and anxiety in the quantitative scale, and intercultural awareness in the qualitative phase. Tajima (2020) cited definitions of intercultural awareness from Merino and Avello (2014) as "how people

become aware of other ways of thinking, living or behaving and how they perceive their experiences with others" (p. 515). Intercultural awareness is referred to as a "prerequisite" for intercultural communication competence.

The researcher used a mixed methods case study design (MM + CSR) which started with a quantitative first phase, followed by a qualitative second phase which involved cases that emerged from the quantitative data analysis. Integration of quantitative and qualitative components took place at the case selection and eventually in the data interpretation stage. Tajima adapted a MM + CSR design from Cook and Kamalodeen (2020). Fig. 1 shows the quantitative phase followed by the emergent 4 cases in the second phase.

Quantitative data were collected from four (4) tests administered pre-departure and post-return from the SA. These were (1) English proficiency—(Computerized Assessment System of English Communication: CASEC), Willingness to communicate, motivation and anxiety. The qualitative data consisted of pre-departure and post-return individual interviews and while-abroad focus group interviews. All interview sessions were conducted using learners' native language, Japanese, then the interview data were submitted to NVivo qualitative data analysis software. The results were translated into English for dissemination by the researcher. Tajima (2020) used NVivo for frequency counts and qualitative analyses of the cases.

Quantitative results were reported in Tajima (2019) as improvement in all constructs measured: English proficiency and affective factors, such as Willingness to Communicate, Motivation, and Language Anxiety after short-term SA. Based on English proficiency test data, four cases were generated from students' language proficiency levels and were utilized to give an understanding of how students' language proficiency influence their understanding and appreciation of the host culture. The proficiency levels were advanced (scores >1200), high-intermediate (scores between 1100 and 1200), intermediate (scores between 1000 and 1100), and low (score <999).

The study confirms that intercultural awareness was not related to English proficiency levels. The findings revealed that higher language proficiency learners did not have enhanced intercultural awareness. As such, students with lower English proficiency seemed more culturally aware. This became evident because the author used a MM + CRS design that allowed for different proficiency cases and investigating each case's typical response. The quantitative data were analyzed based on English proficiency tests and cases generated for an explanation using interviews, which helped to deepen understanding across categories of English proficiency and find explanations and nuances that can help connect second language acquisition and cultural awareness.

Although no paradigm was explicitly declared, Tajima (2019, 2020) used methods that were literature-supported and substantiated research procedures with appropriate citations and good judgment, indicative of a pragmatic worldview. As indicated earlier, pragmatism allows for a researcher in cultural studies in education to use a design they feel comfortable with and answers the research questions on intercultural competence. Language is a definable aspect of culture, and its words refer to internal meanings of its culture (Mazari and Derraz, 2015). The focus of language and perception in a foreign culture in Tajima's study (2019; 2020) shows the intricate role that language plays in cultural studies. We felt that the study would have been enhanced by an explicit declaration of the researcher's philosophical assumptions which, in turn, helps the reader to understand the mixed methods researcher's decisions about the design and integration within the study (Creamer, 2018a; Creswell and Creswell, 2018).

A cross-cultural study in education using MMR

Cross-cultural studies in education involves submerging students and/or teachers in a different culture from their own, for a comparison of cultures in order to understand variations in individual's behavior that is influenced by the cultural context (Papayiannis and Anastassiou-Hadjicharalambous, 2011; Husa, 2021). The study by Ungar and Liebenberg (2011) is an example of a cross-cultural study in education that utilized MMR approach.

Ungar and Liebenberg (2011) illustrated how the application of a transformative MMR design in the investigation of a global cross-cultural study of resilience among children and youth promoted cross-cultural sensitization and equity among diverse cultural identities and languages. The investigation also resulted in the validation of cross-cultural instrumentation and credibility

Fig. 1 Diagram showing the mixed methods case study research design (MM + CRS) of the Japanese Study Abroad program. From Tajima (2020).

of findings. The researchers utilized [Mertens's \(2003\)](#) transformative research paradigm to inform their mixed methods approach, which involved an advanced customized multiphase MMR design that involved sequential, concurrent and embedded designs ([Creswell and Plano Clark, 2018](#)). This design utilized non-linear approaches and methods ([Poth, 2018](#)) to uncover and consolidate the cross-cultural differences related to cultural identities, language and lifestyles among diverse groups of youth and their varied approaches to resilience and resourcefulness.

The researchers collaborated with a team of experts from the Resilience Research Center (RRC) in Canada, to conduct a 3-year, cross-cultural pilot study of child and youth resilience across fourteen communities within eleven countries: Canada, China, Palestine, Israel, Columbia, Russia, India, Florida, Gambia, Tanzania and South Africa. The overarching purpose of the study was to develop a universal Child and Youth Resilience Measure (CYRM-28) that would facilitate inclusion of both minority and majority populations. The researchers set out the following objectives: First, they aimed to create an instrument for the cross-cultural study of resilience that "could account for the psychosocial resources available to youth globally, making cross-cultural comparison of developmental outcomes associated with resilience possible" (p. 127). Second, to discern which internal and external assets most influence successful developmental outcomes across all the cultural groups included in the study. Third, to identify the "elements of a mixed methodology that was effective in the development of culturally sensitive psychological measures that avoided the exporting of concepts from Minority to Majority World contexts" ([Ungar and Liebenberg, 2011](#), p. 127). Their methods were guided by [Onwuegbuzie et al.'s \(2010\)](#) 10-step process for instrument development and construct validation. The aim was "to build a more culturally sensitive measure with face and item validity" (p. 129).

The researchers initiated the study by collecting qualitative data, across multiple sites through consultations with team members, feedback from local advisory committees, focus group discussions with youth and adults in each community, and informal conversations and assessments of youth. The qualitative data were used to develop an initial survey instrument (CYRM-58) for the pilot survey. This is an example of integration with the purpose of "building" ([Creswell and Plano Clark, 2018](#); [Fetters et al., 2013](#)). Subsequent individual interviews were conducted with eighty-nine youth (thirty-two boys, fifty-seven girls) across sites. These youth were purposely selected based on their ability to cope in the face of adversity (e.g., going to school, avoiding drugs and teen pregnancy, attachment to the caregiver).

The qualitative data were analyzed to derive thirty-two domains and four clusters (individual, relational, community and cultural) which were used to develop the CYRM-58. They used factor analysis to analyzed quantitative data which sought to "identify the structure of youth interpretations of the CYRM" (p. 135) which reduce the initial pilot instrument from fifty-eight to twenty-eight items that best represented the construct of resilience across all sites. The qualitative data were also utilized iteratively to investigate the validity of the instrument using students' voices for interpretation/explanation of the quantitative data.

Ungar and Liebenberg reported that the study's findings supported their hypothesis that "Global aspects of resilience (32 domains) can be identified through culturally diverse populations of youth that show unique patterns in how resilience is understood and manifested" (p. 142), and that the results underscore the hypothesized definition of resilience described in the study. The researchers also theorized that resilience is an interplay of individual and context that are reflected by the seven tensions associated with youth outcomes and resilience. These seven "tensions" include: access to material resources, relationships, identity, power and control, cultural adherence, social justice, and cohesion. In response to their third goal, Ungar and Liebenberg posited that through the application of a MMR design supported by the transformative paradigm, they were able to develop an informed, culturally sensitive yet holistic measure of resilience (CYRM-28).

We felt that this study was an appropriate example of the use of MMR in cultural studies in education. The researchers demonstrated integration of both datasets throughout the article, highlighted their research paradigm, stated their MMR goal, and reported using data collection methods that were guided by MMR expert researchers. These help the reader to get a more comprehensive understanding of their research findings. Also important in MMR studies is a rationale for utilizing such a method over others which these researchers provided. They stated:

The use of mixed methods also allowed us to compare the results of our quantitative findings with young people's descriptions of their experiences of complex interactions to nurture and maintain well-being within their challenging social ecologies (p. 128).

They also argued that using mixed method procedures helped to ensure validity of their instrument which would not have been gained had they used a single method.

Relevance of paradigms in promoting cultural diversity and inclusion

Insights gained from the use of MMR in the three selected illustrations in cultural studies in education are now presented relating to the role of paradigms and integration within each unique design. Of the three examples presented, only one declared a paradigmatic position. Ungar and Liebenberg utilized the transformative paradigmatic lens in addressing issues of power and social justice and promoting equity and "voice" across diverse cultural groups. Ungar and Liebenberg reported that this paradigm underlined the development of a culturally sensitized instrument that allowed for inclusion of cultural voices across both minority and majority world contexts and thus reducing cultural bias in the instrument for data collection. While mixed methods researchers such as [Creswell and Plano Clark \(2018\)](#) indicate that pragmatism is most commonly associated with MMR, other paradigms can frame cultural

studies in education to add value and guide the way the study may be designed and conducted. Consistent with the findings of [Alise and Teddle \(2010\)](#) and [Cook and Kamalodeen \(2020\)](#), researchers do not usually declare their paradigm. It is important for researchers to declare their paradigm for the audience as it explicates philosophical assumptions that underpin the methodological decisions of the study.

The purposeful integration of quantitative and qualitative approaches in MMR

Integration is a critical attribute of mixed methods research that distinguishes it from other research approaches. We used descriptions of integration by [Fetters et al. \(2013\)](#) as connecting, building, merging and embedding. Cultural studies in education benefits from the strength of integrating quantitative and qualitative research approaches, thus enabling understanding of the nuances of cultural constructs and contexts. Depending on the MMR design selected in each investigation, integration was enacted at various points in our three examples.

[Acquah and Commins \(2013\)](#) collected data using multiple methods (survey, pre-test and post-test, journals, reflections, final evaluations and focus groups). Integration occurred only in the reporting of the findings. It was clear from the study that the intent for collecting multiple forms of data was to ensure reliability through triangulation and to obtain an elaboration of the quantitative results using the qualitative analysis of data. The authors were therefore able to obtain a comprehensive understanding of the impact of the teaching strategies used in the course on the students' grasp of the principles of multicultural education. Because the quantitative and qualitative were collected simultaneously and one of the intents of the researchers was triangulation, we can infer that the integration using [Creswell and Plano Clark \(2018\)](#) typology was through merging.

[Tajima \(2019, 2020\)](#) initiated her study by analyzing pre- and post- test data to assess the relationship between English language proficiency and the willingness to communicate in English in a Study Abroad program among Japanese students. In the first phase of the study [Tajima \(2019\)](#), four cases of English language proficiency emerged relating to levels of cultural awareness of the host country. Integration occurred through connecting quantitative and qualitative approaches through the sampling frame ([Fetters et al., 2013](#)). The generated cases allowed for a deeper understanding of the meanings of intercultural awareness as it related to communications in English language among non-native speakers in non-native lands. It is clear that the intent of the researcher was development and explanation of the study's quantitative results using a combined mixed methods and case study research approach.

[Ungar and Liebenberg \(2011\)](#) conducted a complex, transformative MMR design to develop a culturally-sensitive global instrument of youth resilience (CRYM-28). To achieve that, the researchers enacted multiple phases of the study that involved the persistent collection, analyses and integration of qualitative and quantitative forms of data. The quantitative instrument was first developed from qualitative data gathered from fourteen sites across the varied participating countries. In addition, qualitative data were used to identify the youth samples for the quantitative pilot study. Following the outcomes from the pilot study, further interviews with the youth were conducted to improve and reduce the instrument. Here, integration was through building. The researchers further validated the instrument by comparing the qualitative construct of resilience with the quantitative data findings. Finally, regarding the interpretation of the quantitative data findings, the researchers then ascertained convergence with the qualitative data from another round of youth interviews. Hence, there was constant interfacing that resulted in intentional integration through building a refined and culturally sensitive universal measure of youth resilience. This study therefore provides insights into the value that MMR integration processes contribute to addressing cultural nuances and consolidating commonalities within cultural studies in education. It also illustrates the level of design flexibility that is afforded the MM researcher to adequately adapt to varied cultural contexts and satisfy the goal(s) of the research. Moreover, there are implications that repetitive rotations of MMR integration in cultural studies will lead to greater clarification of cultural concerns and accommodation of nuances.

Integration in MMR is a purposeful interdependence between the methods within the two research approaches (quantitative and qualitative). The discussions on utilizing paradigms and integration highlight their importance in designing and conducting MMR in cultural studies in education. The illustrations provide evidence that MMR is adaptable to diverse cultural contexts and allow core principles of MMR, once applied, to unravel various layers of the research problems or issues. MMR allows for flexibility in design and methods thus empowering the MM researcher to make optimum research decisions in their "pursuit of truth."

Conclusion

In this chapter, we discussed the use of the MMR approach to investigating issues or problems in cultural studies in education. Cultural studies as a discipline is concerned with the unique and shared ways of living among different communities and contexts. Like integrating multiple methods in MMR, cultural studies facilitate the integration of the various components (beliefs, values, and behaviors) in culture to understand individuals or communities. The integration of data sources facilitates "a more coherent and comprehensive view of what is shared across groups and unique to each other" ([Schrauf, 2018](#) p. 478). MMR facilitates the interrogation of the variances across and within cultures by integrating qualitative and quantitative methods. We shared selected examples to illustrate MMR's utilization in three distinct domains of cultural studies: multicultural, intercultural, and cross-cultural. The open-mindedness that resulted from understanding how culture and ethnicity affect our own beliefs, values, and behavior can lead educators to foster greater respect among cultures in the lecture hall of higher education. The emerging consensus from this paper is that "on the whole, culture can be best explored by employing mixed methods" ([Panda and Gupta, 2013](#) p. 293) because MMR

allows for multiple approaches and fluidity in methodology for examining complex cultural phenomena. Doing culturally relevant MMR, especially underlined by the utilization of appropriate philosophical paradigms in cultural studies in education, can influence the development of culturally sensitive measures and appropriate research methods, leading to socially just and equitable practice.

Introduction

In the field of mixed methods (MM), scholars began writing about MM designs and using typologies since the modern field of MM emerged in the late 1980s (Fetters, 2016). In our own MM projects, we have found design typologies to be frameworks useful for planning and guiding the integration of qualitative and quantitative data collection, analysis, and dissemination to achieve a whole greater than the sum of the individual parts (Fetters and Freshwater, 2015). Here we begin with relevant context in considering mixed methods research (MMR) designs and typologies. We address controversy about creating design typologies, about MM designs being fixed or emergent, and about weighting qualitative or quantitative strands in MMR designs.

Mixed methods research designs combine elements of both the qualitative and quantitative orientations and require creativity and flexibility in their construction as noted by Johnson and Onwuegbuzie (2004) (Tashakkori et al., 2021, p. 114). Authors of typologies include and emphasize differing dimensions especially beyond core designs, and researchers looking for guidance about naming conventions may find the differences among the published typologies to be confusing. Various design typologies fundamentally are similar for three core designs but entail differences in foci as the study procedures and dimensions addressed become more complex.

Comprehensiveness of typologies

Tashakkori et al. (2021) opine that scholars cannot create a comprehensive list of MM designs due to the many possibilities and combinations. We are of the opinion that there are commonly used designs that can be classified and used effectively by MM researchers. We hence value having MM design typologies but acknowledge the immaturity of the field and challenges of creating a complete inventory of MM designs.

Fixed and emergent designs

A contested area in the MM design discourse concerns the question of whether designs should be fixed or emergent. A fixed MM design indicates that the researcher has chosen a design to guide the conduct of the study. In contrast, an emergent MM design indicates that the researcher follows an iterative process in a program of research where the findings after completion of a phase then inform the design of the next phase. An initial qualitative phase might lead to a subsequent phase solely of quantitative data collection, or it could lead to a subsequent phase of both qualitative and quantitative data collection. [Fetters \(2020, p. 66\)](#) argues that the “either/or” dichotomy is arbitrary. Indeed, [Alwashmi et al. \(2019\)](#) describe a hybrid on the fixed and emergent continuum that they call an iterative convergent MM design.

Evidence for the continuum between fixed and emergent comes up frequently. Mixed methods researchers that have chosen in the planning stage a specific design frequently change their data collection procedures in response to emerging findings or change in circumstances. Similarly, a researcher embracing an emergent approach will likely have some “hunch” about what subsequent data collection will encompass. At a practical level, when writing a dissertation proposal or research proposal for funding, reviewers and sponsors of research are unlikely to accept a proposal that suggests the researcher will intentionally conduct subsequent research depending on the findings. Still, sponsors of research also acknowledge the impossibility of anticipating all eventual circumstances at the time a proposal is submitted. For example, many researchers had to change course in response to the COVID-19 pandemic as social distancing measures especially precluded direct observations or interviews. For example, [Bueddefeld et al. \(2021\)](#) changed their original design in response to the COVID-19, a term [Fetters and Molina Azorin \(2021\)](#) refer to as “agile mixed methods.”

Prioritizing strands

A third thread of contentious discussion derives from differences in opinion about handling the priority or emphasis of the qualitative or quantitative strand. Some methodologists opine that in MM studies, either the qualitative or quantitative methodology receives greater priority. For example, Morse characterizes qualitatively driven MM designs as studies with a core qualitative component and an inductive theoretical drive focused on discovery or exploration ([Morse and Niehaus, 2009; Morse, 2015](#)). In the Morse conceptualization of a qualitatively driven design, the secondary quantitative component would not stand on its own ([Morse, 2015](#)). [Hesse-Biber et al. \(2015\)](#) take a less restrictive position recognizing the strength of the secondary quantitative component which lies on a spectrum and could stand independently. [Johnson and Christensen \(2014, p. 671\)](#) characterize quantitatively driven as “a mixed research design in which the quantitative perspective or way of thinking is emphasized and some qualitative data are added to the study.” They also present “equal status” designs where neither component is considered the core driver of the study. [Hesse-Biber et al. \(2015, p. 5\)](#) provided a table that contrasts differences between a qualitatively driven and quantitatively driven approach based on ontology, epistemology, as well as the types of questions, data collected, analysis, and goal. Researchers in the field of MMR generally accept that studies can fall on a spectrum as shown in [Fig. 1](#). The spectrum illustrates that studies can vary in intensity with different degrees of emphasis when qualitatively driven, equivalently driven, and quantitatively driven.

Three categories of mixed methods designs

While consensus is lacking, methodologists in the field of MMR have created design typologies that can fit into the categories of core designs and scaffolded designs. We also include a third category called mono methodology designs. [Table 1](#) uses these three categories to compare the essential variations in MM design typologies through comparison of the methodologists and sources. The table further features the core designs found in common across authors, the array of scaffolded designs with both their degrees of difference and overlap, and the two types of mono methodology designs.

Core mixed methods research designs

Conceptually, MMR methodologists largely agree on three core designs. For the purposes of this chapter, we use the naming convention of [Creswell \(2021\)](#) and [Creswell and Plano Clark \(2018\)](#). These core designs involve (1) collection and analysis of qualitative and quantitative data synchronously—a convergent mixed methods design, (2) collection and analysis of quantitative data where results are used to inform subsequent qualitative data collection and analysis—an explanatory sequential mixed methods design, and (3) collection and analysis of qualitative data where results are used to inform subsequent collection and analysis of quantitative data—an exploratory sequential mixed methods design. These core designs can be used alone to conduct mixed methods

Fig. 1 Spectrum of methodological emphasis in mixed methods research designs.

^aGreene (2007) did not provide a design typology.

studies or used together as “building blocks” to create designs that are even more expansive. For example, they can be integrated with other core designs, with a central philosophical approach, with theory, or with another methodology.

Table 2 illustrates the three core MM designs based on the timing of the collection of the qualitative and quantitative data strands. The table highlights current views and critical features about naming according to major MMR methodologists across multiple disciplines. The listing of the authors roughly occurs in reverse chronology according to the most recently available naming conventions. The following discussion is organized by the authors, and we describe the essential features of each design typology including key changes made by the authors in circumstances where authors changed their naming convention over time, and a critique about strengths and weaknesses for the naming convention.

While there is general agreement on these core designs, naming and typologies vary. Tashakkori et al. (2021) family of designs lumps the latter two into a single category of sequential designs. In our view, the purposes and details of sequential designs have differences of such magnitude that justifies treating them separately. Plano Clark and Ivankova (2016) use abbreviations for classifying the three types of designs, Quan + Qual for a convergent MMR design, Qual to Quan sequential research design, and a Quan to Qual sequential MMR design. Naming conventions have continued to evolve, and it would be prudent to consult the most up to date methodology books to determine naming of a research design in projects, and consider mention of historical analogues as well. In addition to the lack of consensus about naming, another source of confusion about core designs has stemmed from the same authors or groups of authors having changed their own naming conventions over time. In our understanding, this reflects an effort to optimize naming that is precise and intuitive. Ultimately, the differences illustrate evolution of methodologists’ views about elements critical for MMR design naming conventions.

Fig. 2 provides a procedural diagram for each of the three core designs. These follow the convention of Fetters (2020) where a rectangle depicts the quantitative data collection, an oval represents the qualitative strand, and diamond depicts integration of the findings of the two strands. Having portrayed the primary differences in designs and an approach for representing these designs, each design now merits further consideration.

Convergent mixed methods research designs

The hallmark of a convergent design is the collection and analysis of qualitative and quantitative data synchronously, that is, roughly at the same time. While typically separation of the two forms of data collection and analysis is clear, researchers sometimes

Table 2 Core mixed methods designs typologies based on the relationship of the qualitative and quantitative strands.

	Naming convention	Qual and Quan strand relationship		
		Qual and Quan	Quan then Qual	Qual then Quan
Creswell (2021)	Core designs	Convergent	Explanatory sequential	Exploratory sequential
Tashakkori et al. (2021)	Two of the four families of mixed methods designs	Parallel designs	2 sequential	QUAL followed by QUAN
Fetters (2020)	Core designs	-QUAN and QUAL Convergent design	QUAN followed by QUAL Explanatory sequential design	QUAL followed by QUAN Exploratory sequential research design
Creswell and Plano Clark (2018)	Core designs	Convergent MMR design	Explanatory sequential design	Exploratory sequential design
Plano Clark and Ivankova (2016)	Basic mixed methods designs	Concurrent Quan + Qual	Sequential Quan → Qual	Sequential Qual → Quan
Morgan (2014)	Basic designs	Not addressed	QUAN to qual quan to QUAL	QUAL to quan qual to QUAN
Morse and Niehaus (2009)	Qualitatively and quantitatively driven designs	QUAL + quan quan + QUAL	QUAN → qual quan → QUAL	QUAL → quan qual → QUAN
Johnson and Christensen (2020)	Qualitatively/quantitatively driven from equal-emphasis or fully integrative designs ^a	QUAL + QUAN (equal status) QUAL + quan (qualitatively driven) QUAN + qual (quantitatively driven)	QUAN → QUAL (equal status) QUAN → qual(quantitatively driven) quan → QUAL (qualitatively driven)	QUAL → QUAN(equal status) QUAL → quan(qualitatively driven) qual → QUAN(quantitatively driven)

MMR = mixed methods research; Qual = qualitative; Quan = quantitative

^aFetters (2020, p. 212) refers to these as equivalently driven.**Fig. 2** Procedural diagrams for the Three Core Mixed Methods Designs. (A) Convergent. (B) Explanatory Sequential Design. (C) Exploratory Sequential Design.

collect the two strands sequentially, but there is no interfacing until both forms of data collection and analysis have been completed. This latter case would be considered synchronous as the timing relationship in practice is framed by when the two types of data interface.

The procedural diagram in Fig. 2A represents this design. Creswell refers to this as a convergent MM design (Creswell, 2021) though some authors such as Tashakkori et al. (2021) use the language of a concurrent MM design. Teddlie and Tashakkori (2009), previously referred to these as “concurrent parallel designs.” Plano Clark and Ivankova (2016) use Qual + Quan design to denote this type design. Older terminology has included triangulation design. At the time of publication, we perceive that the most up-to-date publications of empirical studies largely use convergent, or to a lesser extent, concurrent for naming. The criticism of the naming convention of convergent is that there is a possibility that the qualitative and quantitative findings may not converge. In response to this criticism, converging the findings does not mean the findings confirm each other, but rather that the two types of data are brought and considered together. In contrast, the criticism of the language of “concurrent” design comes from a nuance that the qualitative and quantitative data collection occurs independently without interfacing with each other. While neither convergent nor concurrent seems perfect as a naming convention, considering the push to emphasize the need for the strands to come together, the language of converging the findings seems most consistent. Converging further does not necessarily mean that the findings must confirm each other.

Longitudinal mixed methods research designs

A special category of convergent designs, the hallmark of longitudinal MMR designs is the collection of both qualitative and quantitative data at multiple time points. [Plano Clark et al. \(2015\)](#) suggested that to be considered longitudinal, these MMR designs should collect both types of data at more than one time point. While having received relatively little attention in most typologies, a growing number of researchers have used these designs. [Kamei et al. \(2021\)](#) utilized a fully longitudinal mixed methods case study design to examine the benefits of telenursing video consultations by examining longitudinal physical and psychological changes in a chronically ill elderly male.

Other variations in naming

As noted, in the rather recent past, the convergent design has been referred to by other names. The use of parallel mixed methods design, parallel concurrent, and parallel convergent mixed methods design, have largely fallen out of favor because of the nuance that parallel lines never join. Some researchers have referred to a triangulation mixed methods design, but this usage has been deemed less effective than the language of a convergent design given the intent of design is to compare rather than to confirm ([Creswell and Plano Clark, 2011](#)). In a more general sense, the place of triangulation in mixed methods methodology has generated considerable controversy, though details of that debate are beyond the scope this chapter's focus on designs ([Mertens and Hesse-Biber, 2012](#); [Fetters and Molina-Azorin, 2017a,b](#)).

Sequential mixed methods research designs

In contrast to the convergent design where in essence the qualitative and quantitative data are collected synchronously, in sequential designs, findings from the first strand can inform the data collection of the second strand. If a quantitative strand such as secondary dataset analysis precedes a second strand of qualitative interviews, findings from the secondary dataset analysis may help formulate questions to ask during the interviews ([Fig. 2B](#)). If a qualitative interview strand precedes the quantitative survey strand, findings from the interviews can be used to build items for the subsequent survey ([Fig. 2C](#)). As [Creswell \(2021\)](#) and [Creswell and Plano Clark \(2018\)](#) developed specific naming conventions that have become broadly recognized, these will be used in the following discussion of core sequential MM designs. As will be seen, the naming convention used by these authors can most easily be understood by considering the function of the qualitative strand.

Explanatory sequential mixed methods research designs

According to [Creswell \(2021\)](#) and [Creswell and Plano Clark \(2018\)](#) a quantitative strand followed by a qualitative strand is called an explanatory sequential mixed methods design. In this design, the initial quantitative strand is used to describe trends across a large population or used to make inferences about causality or correlations ([Fig. 2B](#)). These initial quantitative findings are then explained with a subsequent qualitative strand with a small sample of participants. [Plano Clark and Ivankova \(2016\)](#) refer to this as a Quan to Qual sequential MM design. An example of this design can be seen in a study by [Wong and Cooper \(2016\)](#). They conducted an explanatory sequential MM study by collecting quantitative data from students, followed by semi-structured interviews to explore and explain the students' online learning in Hong Kong.

Exploratory sequential mixed methods research designs

In contrast, a qualitative strand of data collection and analysis followed by a quantitative standard of data collection and analysis is called by [Creswell \(2021\)](#) and [Creswell and Plano Clark \(2018\)](#) an exploratory sequential MM design. In this design, the qualitative strand is used to explore initially a phenomenon before a second quantitative strand that is used to examine the findings across a larger population of participants ([Fig. 2C](#)). [Plano Clark and Ivankova \(2016\)](#) refer to this as a Qual to Quan sequential MM design. [Berman \(2017\)](#) conducted an exploratory sequential mixed methods study by collecting and analyzing qualitative data in the first phase, then conducting quantitative data collection and analysis in the second phase to understand data management behaviors and challenges of faculty at a university in the US.

Scaffolded mixed methods research designs

Scaffolded MMR designs denote research approaches that integrate the core designs with another core design, additional elements, or dimensions. An umbrella term accepted across MM methodologists to categorize this range of mixed methods designs that go beyond the core designs has been elusive. The lack of agreement stems at least in part to variations in the specific elements or dimensions methodologists have chosen to integrate into their design typologies. This expansive category includes multistage designs where two or more core MM designs are used sequentially, analysis-centric MM designs, philosophy-centric MM designs, combined methodology MM designs, and theory-centric MM designs. Each of these are reviewed in detail in the following.

Multistage mixed methods research designs

With multistage MM designs, researchers use two stages or more of data collection. A naming convention for this category is not found in the [Creswell \(2021\)](#) or [Creswell and Plano Clark \(2018\)](#) typologies. [Tashakkori et al. \(2021\)](#) refers to this family of designs

as hybrid designs. They use the language of hybrid to indicate combining two or more of what they call three basic families of designs (i.e., parallel MM designs, sequential MM designs, and conversion MM designs). [Fetters \(2020\)](#) and [Fetters and Kakai \(2021\)](#) use the language of compound designs to refer to combining two core designs together sequentially. The rationale for compound design is adapted from chemistry where two elements can be combined into compounds. While the resulting compound may have some similar properties to the elements from which it was made, the resulting compound will take on new characteristics or prospects not found in the individual elements. The language of multi-core designs has also surfaced in discussion with colleagues, though this language only expresses a multitude of core designs being used together while compound has the nuance of new properties.

The language of a multistage MM design represents the most generic of terms to indicate a study using multiple stages of research with various combinations of qualitative and quantitative strands. When multiple studies are used together, these may amount to mixed methods programs of research ([Crabtree et al., 2011](#)). Many multistage designs may have additional elements that can be in combination with a strongly emphasized analytic approach, philosophical stance, or theory. In such a case, we advise incorporating the language of the additional element of emphasis rather than just multistage design as this will be more specific and more comprehensible by readers.

Analysis-centric mixed methods research designs

The [Tashakkori et al. \(2021\)](#) family of designs typology includes a category of conversion MM designs. In their description of this design, they state, "In conversion MM designs, mixing occurs when one type of data is transformed and analyzed accordingly (thematic or statistical) to answer related aspects of the same research question." (p. 128). This family of designs most typically involves quantizing, where qualitative data are converted into numerical codes or categorical variables for analysis statistically with quantitative data from another strand. Hence, qualitative data converted or transformed into a quantitative or categorical form would then be combined and manipulated with other quantitative data for the analysis ([Sandelowski et al., 2009](#)). [Seltzer-Kelly et al. \(2012\)](#) utilized quantizing in a curriculum efficacy study of the diversity component of an undergraduate-level arts and humanities course. While it occurs far less frequently, qualitzing is the process of transforming quantitative data into data that can be analyzed qualitatively like a theme ([Onwuegbuzie and Leech, 2021](#)). [Weaver-Hightower \(2014\)](#) utilized a five-stage, embedded MM design for establishing influence on educational policy through an analysis of Australia's policy making on boys' education that featured both quantizing and qualitzing, within a larger qualitative study.

[Tashakkori et al. \(2021\)](#) are the only widely published methodologists who characterize an analysis-based approach to qualify as a design category. The lack of support by other methodologists of these as design categories seemingly stems from the point that data transformation is an analytic procedure that could be used in any of the other MM designs. Thus, in a study that has collected qualitative and quantitative data it would be possible to transform qualitative data into a quantitative form for analysis as quantitative data for a first analysis. Additionally, the researcher can transform the quantitative data into a qualitative form for analysis as qualitative data within the same study.

Take the case of a convergent design, or concurrent design as named by [Teddlie and Tashakkori \(2009\)](#) with roughly synchronous collection of both qualitative and quantitative data. Using the same qualitative and quantitative dataset, researchers hypothetically could conduct (1) a mixed data analysis without conversion, (2) a qualitative to quantitative data conversion for analysis quantitatively, and (3) a quantitative data to qualitative data conversion for analysis qualitatively. Under this hypothetical scenario, the authors would be using the same qualitative and quantitative datasets but with three different designs, including two different conversion designs. Rather than characterize the analytic approaches as specific designs, it would seem much more efficient and informative to refer to this as just a convergent design or concurrent design, which would be the same for all three situations, but be illustrative of three analytic strategies. This example supports the assertion that data transformation is an analysis strategy rather than a design category.

Philosophy-centric mixed methods research designs

We characterize philosophy-centric designs as approaches whereby researchers explicitly incorporate the world view throughout all dimensions of integrated qualitative and quantitative data collection, analysis, and dissemination to achieve an agenda set forth and framed by the world view at the outset of the study. Though extensive discussion falls beyond the scope of this chapter, historically, the field of MM experienced a period known as the paradigm wars. The essence of this debate could be distilled down to what many have called the incompatibility thesis, namely, that the post-positivist philosophical grounding of quantitative research differed from a constructivist philosophical grounding of qualitative research. After intensive debate and rhetoric, to date, seven major worldviews have been articulated in the literature that support integration of qualitative and quantitative strands as MMR. These seven include pragmatism, participatory/transformational, critical realism, postmodernism, yinyang, dialectical pluralism, and performative paradigm. The philosophical stance explicitly, or often implicitly, drives the choice of methodology and methods ([Greene, 2015](#)).

While philosophical assumptions or worldviews underlie all MM studies, the degree authors are explicit or implicit about this varies dramatically across disciplines. Mixed methods researchers could make their designs philosophy-centric through careful articulation of their assumptions in a variety of MMR dimensions. Still, as illustrated by [Coates \(2021\)](#), only a fraction of education researchers expressed explicitly their philosophical assumptions in published MM studies, and in many cases, these were mentioned

Table 3 Philosophy-centric mixed methods research approaches.

	<i>Design</i>	<i>Definition</i>	<i>References</i>
Social justice	Transformative	The transformative paradigm brings together many philosophical strands where social justice operates as a first principle in research endeavors.	Mertens (2003, 2009)
	CBPR	CBPR researchers consider the community as the unit of identity, build on strengths and resources of the community, seek equitable partnerships, foster <i>capacity building among all partners</i> , balance knowledge generation and intervention for the mutual benefit of all partners, leverage systems development using a cyclical and interactive process, and disseminate results to all partners in a long-term process with a commitment to sustainability.	Israel (2013)
Pragmatism	Action research	Action researchers engage in a participatory process with the intent of generating practical knowledge that can enhance human lives by integrating action, reflection, theory, and practice in their efforts to identify practical solutions for peoples' real-world problems and for their communities.	Reason and Bradbury (2008)

superficially without indicating how the assumptions influenced the study. Accordingly, the MM literature includes designs that explicitly drive the collection of MM data rather than justifying the collection of both strands of data. For the purposes of this chapter, these are referred to as philosophy-centric MMR designs. Creswell and Plano Clark (2018) include this type of design in their typology of complex designs. Plano Clark and Ivankova (2016) recognize this type of design as an intersected design. Fetter's (2020) categorizes this design under the rubric of a scaffolded design.

Table 3 illustrates two philosophy-centric approaches, namely social justice-centric designs and pragmatism-centric designs, as well as illustrative examples.

Social justice-centric mixed methods research

These studies can be characterized as approaches to inquiry that integrate qualitative and quantitative methods and are guided by a worldview that values and nurtures a commitment to collaborating with and incorporating as equals the voices of individuals from the population that is the focus of the inquiry. There is an explicit intent of promoting equity, fairness, and mitigation of discrimination. Researchers employing social justice-centric MM emphasize a particular ethic of inclusion relative to advocacy, equality, and participation of populations who are a central focus in the research as partners for determining the research undertaken, the methods to employ for the data collection, the framing of the analysis, and choices about dissemination.

Two social justice-centric MMR approaches have become widely recognized and utilized. These approaches include transformative MMR and community-based participatory research (CBPR). With both approaches, MM researchers make a commitment to including individuals from the study population into the research. Each has unique features as shown in Table 2. Rather than being specific in their data collection procedures, analysis, and dissemination, researchers using these philosophy-centric MM approaches utilize a variety of methods, qualitative and quantitative to achieve their goal of a more just society.

Transformative mixed methods research designs

Transformative MMR designs conceptually reflect approaches to the integration of qualitative and quantitative data collection, analysis, and dissemination where the researcher's choices are fundamentally driven by an explicit recognition that social injustice pervasively influences the phenomenon. With the intent of challenging social justice issues and emancipation, the research actively and intentionally chooses methods perceived as most useful for mitigating the injustice of the marginalized population of interest. Mertens (2015, p. 307) pioneered the MM transformative paradigm by contrasting the approach with post-positivism and constructivism. She emphasizes how MM procedures can empower researchers to address the complexity of issues of human rights and social transformation (2015, p. 306). Conducting a transformative MMR study involves using this transformative worldview with MM methodology. Mertens et al. (2010) stated:

The philosophical assumptions of the transformative paradigm led to consideration of approaches to research that reflect explicit recognition of values and knowledge of self and community that form a basis for methodological decisions (p. 195).

In short, the researcher has a philosophical commitment to addressing unjust sociopolitical problems and achieving social justice through sociopolitical solutions. For example, Camacho (2020) examined the workplace experiences of academic migrants, that is, international postdoctoral scholars who despite comprising a large percentage of the academic workforce experience low paying positions, limited employment stability, disparate degrees of rights and freedoms, and reputation fragility. She sought achievement of better work conditions for this population through her use of a transformative MM approach with systematic attention to criteria Mertens (2003, 2009) identified as essential for a MM transformative design.

Community-based participatory research mixed methods designs

Community-based participatory research using MMR represents a second philosophy-centric MMR design category. Like transformative MMR, CBPR using MMR signals a philosophical commitment to engaging as equals community members to achieve social justice. CBPR studies most typically focus on research about health, but also education. CBPR MMR designs refer to approaches to the integration of qualitative data collection, analysis, and dissemination where the research engages community representatives as partners throughout the entire research endeavor from identification of the research agenda, etc. While CBPR researchers frequently use a combination of qualitative and quantitative strands, CBPR studies might use solely qualitative or quantitative research. Arguably, CBPR represents a methodology as well as philosophical commitment. However, the central and explicitly driven emphasis on a social justice agenda at the community level favors categorization of this approach as a philosophy-centric approach rather than just a methodological approach being combined with MM methodology. Upadhyaya et al. (2015) conducted a CBPR project with doctoral students, community leaders, and faculty collaboration in teaching, learning, and research in all stages of the project on health research and education.

Integrating transformative mixed methods and community-based participatory research

A transformative lens can be used for the underlying philosophical grounding for a community-based participatory research study. For example, Maleku et al. (2021) used a transformative lens in their research with African refugees in the southern United States to examine the intersection of culture, financial stress, and financial self-efficacy, and then tested a culturally responsive solution to financial literacy based on community-identified priorities. In addition to scaffolding the study with the transformative lens using a CBPR approach, they employed an explanatory sequential MMR design to conduct their research in a cross-cultural context. This example illustrates how the two approaches are both compatible with each other as well as how the transformative MM component provided a lens that was implemented through use of a CBPR approach.

Pragmatism-centric mixed methods research

Pragmatism-centric MM studies represent another example of a philosophy-centric MM design. Pragmatism-centric studies integrate qualitative and quantitative methods and are guided by pragmatism (Morgan, 2014). These studies are focused on addressing practical, real-world problems, and identifying practical solutions for improving the lived reality of the population of interest. While there may be an underlying intent for achieving advocacy, equality, and participation of populations who are a central focus in the research as partners for determining the research undertaken, the researchers use of applied and practical approaches for conducting the data collection, analysis, and dissemination distinguish the approach from a social justice-centric intent.

Action research mixed methods

Action research mixed methods represents an excellent example of a pragmatism-centric research approach with increasing recognition and use. Action research is defined by Reason and Bradbury (2008) as:

... a participatory process concerned with developing practical knowing in the pursuit of worthwhile human purposes. It seeks to bring together action and reflection, theory, and practice, in participation with others, in the pursuit of practical solutions to issues of pressing concern to people, and more generally, the flourishing of individual persons and their communities (p. 4).

In the most recent edition of the SAGE Handbook of Action Research, Reason and Bradbury (2008) described action research as a “family of practices of living inquiry that aims, in a great variety of ways, to link practice and ideas in the service of human flourishing” (p. 1).

Participatory action research is one variant of many action research designs. Action researchers embrace a pragmatic approach with the intent of solving real-world problems. It has a practical focus, community-based orientation, participatory and collaborative nature, emphasis on empowerment, and values of reflection (Reason and Bradbury, 2008, p. 27/452).

Mixed methods researchers have harnessed the power of action research with CBPR and MM. For example, Garnett et al. (2019) used a transformative MM study design to examine the emancipatory potential of incorporating youth participatory action research and restorative practices implementation in a high school. In this study, the transformative MM component provided critical consciousness among students, families, staff, and administration in high schools and evaluation of restorative practices using a youth participatory action research approach (Garnett et al., 2019).

Combined mixed methodology research designs

The 2010s marked rapid uptake and advances in designs created from using mixed methodology combined with another methodology. Given the seemingly innumerable types of designs used by qualitative and quantitative researchers, this advance of combining MM methodology with another type of methodology naturally led to expansion of possibilities with MM methodology. In a special issue in the American Behavioral Scientist, Creamer and Schoonenboom (2018) proposed the language of inter-method

mixing for these designs. We have opted to use the language of combined MM methodology research designs as inter-method mixing refers to the process, and the language is not conducive to a compound noun for a name in a typology.

In the broader typologies of the authors featured in this chapter, Creswell (2021) and Creswell and Plano Clark (2018) include this combination of designs in their category of complex designs. While not defined as such by the authors, these designs would presumably fall under hybrid designs in the family of designs typology by Tashakkori et al. (2021). Fetters (2020) includes these combinations as scaffolded designs. Plano Clark and Ivankova (2016) include this combination as an intersected design. Some examples of qualitative methodologies integrated with MM include case study (Guetterman and Fetters, 2018; Bustamante, 2019), grounded theory (Shim et al., 2017, 2021), phenomenology (Martiny et al., 2021; Clark-Gordon et al., 2017), phenomenography (Roberts, 2003), narrative (Waller et al., 2021), art-based inquiry (Archibald, 2018; Archibald and Gerber, 2018), and ethnography (Kaczmarczyk and Salamońska, 2018; Berthod et al., 2017; Crede and Borrego, 2013). Some examples of quantitative methodologies integrated with MM include quasi-experimental designs and experimental designs (O'Cathain, 2018; Creamer et al., 2021).

In the process of integrating other methodologies with MM, methodologists have noted that the “added” methodology might be a component of a MM study, or that MM might be used carrying out a different methodology. Consequently, researchers have begun to divide these combined methodology designs according to (1) using the additional methodology as a component of a MM study, or (2) using MM procedures to conduct the alternative methodology. The first group involves MM using a specific qualitative methodology when conducting the qualitative component of a MM study. The second group involves MM to support the overall study. To understand this distinction, take for example the combining of case study methodology with mixed methodology. A MM study might employ the use of a case study for the qualitative component. Guetterman and Fetters (2018) denoted this as a mixed methods-case study (MM-CS). In contrast, a case study might employ the use of MM to conduct the study. Guetterman and Fetters (2018) referred to this as a case study-mixed methods (CS-MM) design.

While a broadly accepted naming convention is lacking, we suggest methodologists adopt a naming convention where both MM and the additional methodology names are found in the design name. We propose the order of naming should reflect first the component most reflective of the overarching purpose, and the second component to indicate the supportive component being used. Conceptually this could be understood by using the hyphen to signify the meaning of “using.” Hence, mixed methods-grounded theory (MM-GT) would denote MM using grounded theory for the qualitative component as illustrated in Fig. 3A, and grounded theory-mixed methods (GT-MM) would denote a grounded theory study using MM as shown in Fig. 3B. Grounded theory studies are typically qualitatively oriented. However, GT-MM incorporates both qualitative and quantitative data within an overarching grounded theory study.

Taken a step further, methodologists could be even more specific and descriptive. As noted in a Fig. 4A, a MM-GT study using a convergent MM design would be called a convergent MM-GT design. The quantitative strand and grounded theory qualitative strand findings are merged. As in Fig. 4B, a MM study using an explanatory sequential MM design could be called an explanatory sequential mixed methods-convergent design. In the first quantitative phase, quantitative data are collected and analyzed. In the qualitative second phase, the grounded theory methodology is used to build theory about quantitative results from the quantitative first phase. Finally, as in Fig. 4C, a mixed methods exploratory sequential MM design would thus be called an exploratory sequential MM-GT design. Within the qualitative first phase, theory building takes place via grounded theory methodology, while in the second quantitative phase, the theory is tested using a quantitative approach. At this point in the field of MMR, only a small number of authors have utilized some of these designs. While far from comprehensive, Table 4 provides multiple examples of combined mixed methodology research designs.

A detailed examination of all the studies in Table 4 that depicts many examples of combined methodology MM designs is beyond the scope of this chapter. That said, it is safe to say that the combined methodology examples provided are just a beginning to the variety expected to emerge.

For example, Feldon and Tolfel-Grehl (2018) introduce phenomenography MMR, where phenomenography involves framing personal conceptions as a necessary construct to related physical events experienced by people and the personal meaning of those experiences. They provide three examples of phenomenography used with the three core designs, an exploratory sequential MM design, an explanatory sequential MM design, and a convergent (concurrent) MM design. Mayoh and Onwuegbuzie (2015) provided five models for MM phenomenological research. They based the typology on purposes of the study and the priority within the study design.

Archibald and Gerber (2018) illustrated four categories of integration of arts-based research and MMR. They identified (1) communicative integration, namely, the use of arts to express MM findings; (2) data source integration where arts are used as qualitative or quantitative data integrated with the other type of data, (3) analytic integration where arts are used to enhance understanding of mixed data, and (4) conceptual integration where arts-based and MM approaches are integrated to illustrate constructs, concepts, theoretical, analytical, and methodological dimensions of a study.

Theory-centric mixed methods research designs

Researchers use theory in a variety of ways in their investigations. When theory underlies the approach of the MM study, researchers are using a theory-centric MM design. Implementation science uses many different theories to inform the data collection (Dam-schroder et al., 2009). Researchers guided by complexity theory also utilize precepts of the theory to consider the complex adaptive systems about which they conduct research. While not acknowledged in Tashakkori et al. (2021) typology, Creswell and Plano Clark

Fig. 3 Two approaches for Combining Mixed Methods and Grounded Theory. (A) Mixed Methods using Grounded Theory (MM-GT). (B) Grounded Theory using Mixed Methods (GT-MM).

Fig. 4 Three Core Mixed Methods Designs using Grounded Theory (MM-GT). (A) Convergent MM Grounded Theory Design. (B) Explanatory Sequential MM Grounded Theory Design. (C) Exploratory Sequential MM Grounded Theory Design.

(2018) would include such designs in their category of complex designs. Plano Clark and Ivankova (2016) identify this as an intersected design while Fetters (2020) considers this a scaffolded design. In a widely cited paper, Peters et al. (2013) defined implementation research in the health sciences as "... the scientific inquiry into questions concerning implementation—the act of carrying an intention into effect, which in health research can be policies, programmes, or individual practices (collectively called interventions)."

In the implementation science field, researchers typically use theory to evaluate interventions. Chu et al. (2021) conducted a convergent MM process evaluation of a clustered-randomized controlled trial to determine the effects of a sodium reduction program in 120 rural villages in Northern China. The investigators used multiple qualitative and quantitative approaches guided by process evaluation theory to examine fidelity, delivery, reach, and receptivity of the intervention, as well as contextual factors to evaluate the clustered-randomized controlled trial.

Mono methodology mixed methods designs

As noted in Table 1, most MMR methodologists do not include mono methodology MM designs in their typologies. For the purposes of this chapter, mono methodology MM designs are defined as research strategies that utilize one approach to collection of both qualitative and quantitative data, or research strategies that collect data in one form that is analyzed using both qualitative and quantitative procedures. We accept this broader view since MM researchers commonly use these procedures to collect and analyze mixed data. Hence, these procedures use either "mixed methods" data collection, or "mixed methods" analysis. The data collection strategies and analytic strategies devised by MM researchers for integration are particularly apropos and can lead to richer interpretations.

Table 4 Designs combining mixed methods and other methodologies.

<i>Design variation</i>	<i>Description</i>	<i>Example</i>
Case Study-Mixed Methods (CS-MM)	Case study approach using mixed methods	Hall and Ryan (2011) conducted a case study that further used exploratory sequential mixed methods design where Phase 1 preliminary document reviews, interviews, and observations were used to build, then conduct a survey for a deep understanding of the survey findings.
Mixed Methods- Case Study (MM-CS)	Mixed methods study approach using case study as the qualitative strand	Onwuegbuzie and Leech (2010) conducted a mixed methods case study fully integrated throughout multiple dimensions initial quantitative assessment to examine the frequency authors of qualitative articles made generalizations in the journal <i>Qualitative Report</i> . They then conducted a subsequent qualitative assessment to assess the kinds of over-generalizations made in recommendations, and illustrating interpretive inconsistency based on the mixed methods analysis.
Grounded Theory- Mixed Methods (GT-MM)	Grounded theory approach using mixed methods	Shim et al. (2021) in Phase 1 constructed a theoretical model based on the literature through <i>meta-modeling</i> . In the second part of Phase 1, they used a classical GT model describing the mechanisms of dance movement therapy for resilience building in people with chronic pain based on in-depth interviews. We made every effort for this GT process to be independent of the initial formative model, so that the GT could freely emerge from the qualitative interview data because this is ... Shim et al. (2021) reported using an exploratory–confirmatory MM-GT design. The authors characterized their study as an exploratory–confirmatory MM-GT design.
Mixed Methods- Grounded Theory (MM-GT)	Mixed methods study using grounded theory for the qualitative strand	Howell Smith et al. (2020) utilized an exploratory sequential instrument development design study to develop and test a theoretical model. The first phase was a qualitative grounded theory to develop a theoretical model of constructs. The second, instrument development phase, developed a measurement instrument to test hypotheses related to the theory generated in the qualitative phase. The third phase was used to collect data from a larger sample. The fourth phase integrated the quantitative model-fit results with the grounded theory model to finalize an empirically tested theoretical model.
Phenomenology-mixed methods	Phenomenology using mixed methods	Martiny et al. (2021) discussed application of phenomenology-mixed methods in both experimental settings and in clinical settings. They provided three examples of applications in understanding the real-life experience of joint musical absorption by musicians, how to create and investigate positive and negative experiences of joint actions in cerebral palsy, and how to change and investigate prejudicial attitudes toward disability.
Mixed methods- phenomenology	Mixed methods study using phenomenology for the qualitative strand	Clark-Gordon et al. (2017) used an exploratory mixed-methods approach to explore college students' use of novel social media platform that was followed with a subsequent quantitative content analysis of postings to examine distribution of posting types.
Ethnography-mixed methods	Ethnographic study using mixed methods data collection	Kaczmarczyk and Salamóńska (2018) examined migration from Poland utilizing ethnosurvey methodology, an approach characterized as integration of ethnographic and survey approaches that iterates between quantitative and qualitative modes during design, data collection and analysis.
Mixed methods- ethnography	Mixed methods study using ethnography for the qualitative component	Crede and Borrego (2013) conducted an exploratory sequential mixed methods design where an initial ethnography was used as the qualitative approach and used the resulting themes to create constructs and survey questions for instrument was used to examine retention of graduate engineering students.
Narrative-mixed methods	Narrative research using mixed methods data collection	Waller et al. (2021) examined longitudinal data from the Fragile Families and Child Wellbeing study to create narrative case histories. They used a longitudinal mixed methods design to construct narrative case histories from survey data that they grounded in parents' qualitative accounts to achieve a better understanding of survey outcomes.
Mixed methods- phenomenography	Mixed methods study using phenomenology	Roberts (2003) conducted an explanatory sequential design with an initial mixed data collection survey about instructors online teaching practices followed by qualitative interviews using phenomenography.
Visual media-mixed methods	Photo elicitation MM study design	Peroff et al. (2020) utilized a photo elicitation mixed methods study design to assess residents' place attachment to the Guatemalan Maya Landscape. The authors integrated quantitative rankings of photos with qualitative interpretations of Guatemalan residents' perceptions of the meanings of the photos.

Mono methodology mixed data collection designs

Mixed data collection designs commonly used include survey research methodology and secondary dataset abstraction. Surveys commonly include a series of close-ended questions of categorical or continuous data as well as open response items including comments. The quantity and quality of qualitative data collected this way are often, but not always lacking in the true spirit of qualitative methods that seek thick and rich descriptions. Still, in many cases, the collected qualitative data prove invaluable as collecting the data allows respondents to explain choices, or raise critical issues not systematically examined by researchers in the close-ended items or questions. [Creswell and Plano Clark \(2018\)](#) have described this form of mixed data collection as “mixed methods light” as the qualitative component falls short compared to use of more intense procedures such as interviews or observations that would permit in-depth collection of qualitative data. Data abstraction methodology of secondary datasets represents another example of mixed data collection as this process involves retrieving both qualitative and quantitative data from an existing dataset.

Mono methodology mixed data analysis designs

Mixed data analysis designs involve converting quantitative data into qualitative data and/or converting qualitative data into quantitative data. Converting quantitative data refers to transforming quantitative data into narrative data to be qualitatively analyzed. This is often referred to as quantitizing ([Tashakkori et al., 2021](#)). Qualitative data can be converted into numerical codes or categorical variables to be statistically analyzed. This can be referred to as qualitizing ([Tashakkori et al., 2021](#)). The defining issue of such designs is the transformation of the originally collected data into the other format of data that is then followed by comparison of the qualitative and quantitative formats of data. For example, quantized data are compared with qualitative data. Video data, SMS text data, online forum data all serve as examples of data that are manipulated by the researcher from the original material, e.g., visual video data or audio data from videotaped encounters, into various forms of qualitative and quantitative data, e.g., transcripts or observations and time on topic or frequency counts of mentions of specific concepts, respectively.

For example, [Ruffin et al. \(2009\)](#) conducted research to understand the perspectives of individuals who were eligible for colon cancer screening, but had not been screened with the intent of creating a website chooser that would allow unscreened individuals to choose among acceptable screening approaches. The research team conducted focus group interviews, and for their analysis they coded and quantified the various responses that were elicited during the focus group interviews while also providing a series of quotes for each construct that represented the range of responses in a joint display. This mixed data analysis and comparison illustrated the most common issues vocalized as well variations in how participants expressed their opinions with representative quotations by different demographic groups. [Chang et al. \(2021\)](#) conducted mixed data analysis of SMS messages from adolescents to understand their perspectives of the evolving COVID-19 pandemic.

Variations in naming conventions

[Teddlie and Tashakkori \(2009\)](#) distinguished between mixed designs and quasi-mixed designs. According to their definition, quasi-mixed designs involve collection and analysis of both Quan and Qual data, but no mixing of the methods or the results. In our conceptualization of the two monomethodology designs, they are not quasi because there must be integration of qualitative and quantitative forms of data. Critics of categorizing the two monomethodology approaches under the mixed methodology umbrella of designs could argue that a MM study must include the collection and analysis of both qualitative and quantitative data. In the case of the monomethodology design, the concern relates to the quality of the collected data, especially the qualitative data. While conceding that the data collection is achieved through use of only one methodology, the kinds of sophisticated mixed data analyses that authors are using in studies of large qualitative datasets accentuates the relevance to MM approaches to analysis such as the use of joint displays as was the case in the research of [Ruffin et al. \(2009\)](#).

Conclusions

In this chapter we considered typologies of MM designs developed by MM methodologists across many published MM studies. In the broadest categorization, we identify core MM designs, scaffolded MM designs, and mono methodology MM designs. In the following, we synthesize contested areas about mixed methods designs.

Caveats and controversies about the use of mixed methods designs

When considering a particular design and design typology, one needs to carefully consider the specific dimensions that the author of the typology has considered. For example, in [Tashakkori et al. \(2021\)](#), the typology is organized by not only timing of different components, but also sampling and analysis. CBPR and transformative MM designs largely infer a social justice agenda where the description of designs used is in service of the philosophy. Likewise, in implementation research, theory guiding the evaluation is critical.

The scaffolded designs category builds and expands upon previous efforts to categorize diverse dimensions that we characterize by their nature of being focused on multiple stages, analysis, philosophy, methodology, and theory. Mixed methods researchers

continue to experiment with utilizing several of these different MMR designs together. For example, Ling and Pang (2021) conducted a multiphase quasi-experimental study using vignette-based MM and phenomenology in an interventional study examining financial education of early adolescent ethnic minority students. The authors used a philosophy-centric approach as a transformative lens provided the framework for their study. They further used a combined MM design as they employed through methodologies in their study, (1) a quantitative intervention, (2) a mono methodology mixed data collection survey, and (3) qualitative data collection guided by phenomenology. What remains unclear is how to name designs that incorporate several of these dimensions.

We have argued that mono methodology research qualifies as MMR as these designs call for methods for analyzing both qualitative and quantitative data. We acknowledge our stance as controversial. Plano Clark and Ivankova (2016) explains the importance of this distinction when reading published empirical mixed methods studies. Fetters and Molina (2017a) captured this notion of quasi-MM studies with the equation of $1 + 1 = 2$ where the sum of the two strands is cumulative, and contrasts with $1 + 1 = 3$ to indicate that study will produce a whole as a MM design that is greater than the sum of the individual components.

We did not conduct a systematic review to include all designs, nor a comprehensive history of design typologies. While we have provided several examples of how typologies have evolved, a full treatise on how all design typologies have evolved overtime extends beyond the scope of this chapter. Creswell and Plano Clark (2018) included information on how and why their designs and typology evolved overtime.

Despite the gains in maturity of the field of mixed methods research (Fetters and Molina-Azorin, 2021), many innovations have been and will continue to occur. We interpret changes as healthy if the thinking reflects a better conceptualization or expression. While acknowledging the importance of identifying the source of a concept or idea, forcing innovative thinking to fit with the use of the pre-existing language may be unhealthy for the field (Fetters and Molina-Azorin, 2017b). Still, once novel procedures become mapped, the field also benefits from consistency of naming conventions to facilitate comparisons.

In sum, while MM core designs are acknowledged across most methodologists, variations in naming = remain published typologies. Views diverge about MM designs categorizations beyond the core designs and are even less homogeneous than core designs. This chapter advances the literature through the organization and articulation of five types of scaffolded MM designs. These include multistage MM research designs, analysis-centric MM research designs, philosophy-centric MM research designs, combined methodology MM designs, and theory-centric MM designs. We advocate acceptance of two types mono methodology designs: mixed data collection mono method designs and mixed data analysis designs. The advancement of MM research lies in having rhetoric to describe research methods of their studies. Despite many advances in the field, opportunity abounds for further innovations in MMR design.

Mixed methods research, the joint use and integration of qualitative and quantitative approaches, methods, and data, has a much longer history than is usually acknowledged in the self-identified “mixed methods” literature (Maxwell, 2016). In addition, mixed methods approaches are widely used in social science fields that are rarely recognized in this literature (Maxwell, 2018). This chapter will draw on both of these sources to address how to design integration in mixed methods research.

My argument in this chapter is based on an analysis of the differences in goals between quantitative and qualitative research, and the implications of these differences for research design and methods. In terms of goals, quantitative research is primarily focused on the effect of some variables or interventions on other variables or outcomes. Qualitative research, in contrast, aims more to understand the processes (including mental processes) involved in an individual or social setting, and how these are influenced by the context in which that individual or setting is located. These differences result in different strengths and limitations for each approach in dealing with two important issues in social research: the analysis of causation, and the generalizability of the results.

The concept of “design” also requires some discussion. There are various conceptions of “design” in the research literature, with major differences between quantitative and qualitative research. Experimental research has largely adopted a typological approach to design, creating multiple designs that vary in how subjects are assigned to conditions and when variables are measured. Non-experimental quantitative research lacks such an elaboration of typologies, but most such studies share an important feature of research design with experimental research: that the research parameters are established in advance of data collection, and can’t be altered during the study, in order to ensure the comparability of the data for aggregation and analysis. Robson (2011) referred to such inflexible approaches as “fixed” designs (Exploratory analysis of quantitative data, however, is flexible and widely used [Robson, 2011, pp. 419–420]).

Qualitative research, in contrast, has largely avoided typological thinking about design, since its main strength is the adaptability of its data collection and analysis procedures in response to unanticipated events or findings; Robson (2011) labeled these “flexible” designs. However, qualitative researchers have typically been much less explicit about the concept of design. Schwandt (2007) stated that

Designs or plans for conducting qualitative studies vary considerably; there are no prescribed designs as, for example, one might find in survey research, experimental, and quasi-experimental studies in the social sciences (p. 273).

Some qualitative textbooks (e.g., Glesne, 2016) don’t use the term “design” at all; others mention research design only in vague terms. Mason (2018) describes a more explicit approach to “qualitatively-driven research design,” addressing the intellectual puzzle, theoretical orientation, methodological approach and research strategy, data analysis, and ethical considerations (pp. 49–50), but with no attempt to identify “types” of designs.

Self-identified “mixed methods research” has largely followed a typological approach to design, identifying an array of design types that can be adopted by researchers, delineating the dimensions on which mixed methods studies can vary and identifying the possible and actual combinations of qualitative and quantitative methods. Caracelli and Greene (1997) identified two basic types of mixed method designs, which they called “component” and “integrated” designs. Component designs are ones in which “the

methods are implemented as discrete aspects of the overall inquiry and remain distinct throughout the inquiry”, while integrated designs involve “a greater integration of the different method types” (pp. 22–23). Within these broad categories, they describe seven subtypes, based largely on the goals for combining methods. More recently, [Creswell and Plano Clark \(2018\)](#), [Mertens \(2018\)](#), and [Tashakkori et al. \(2021\)](#) presented more elaborate typologies of design, involving the order in which the qualitative and quantitative methods are used, the relative dominance of the two approaches, and the degree of integration.

In contrast, researchers outside of this self-identified community, in fields such as political science, anthropology, linguistics, education, and many of the natural sciences ([Maxwell, 2016, 2018](#)), who were integrating quantitative and qualitative approaches and methods long before the term “mixed methods” was coined, have largely avoided typological thinking about design. In this, they are similar to qualitative research. Johnson, in what is apparently the first textbook on designing such integration (1978), did not explicitly define “research design,” but simply stated that “the purpose of research design is to use theoretical arguments to develop expectations about the world, and then to test them by collecting empirical data” (p. 2). [Gorard \(2017\)](#), primarily addressing quantitative research, defined research design as “the structure and organization of a research project” (2017, p. 203).

An interactive concept of design

In the present chapter, I use a broader conception of design than that common in self-identified mixed methods research ([Maxwell and Loomis, 2003](#); [Maxwell, 2013](#)). Webster’s Collegiate Dictionary (1984, p. 343) defined this conception of design as “an underlying scheme that governs functioning, developing, or unfolding” and “the arrangement of elements or details in a product or work of art.” This is the meaning of “design” in everyday use, in referring to the design of a building, a machine, or a work of art. Applied to research, this conception is of design as the actual relationships among the components of a study, not just a categorization of the study as a particular type of design, or as a fixed sequence of steps in conducting the study.

This approach to design focuses on the components of a study, and how these interact with one another in the planning and conduct of the research. For this reason, I originally labeled this an “interactive” approach to design, but the term “integrative” is equally appropriate, as the different components need to be integrated with one another in order to function effectively. This meaning includes not just the planned design of a study, but also the actual design of the research “on the ground,” which may differ from the planned design, and even from what the researcher claims or believes about the design, and may change during the course of a study.

This conception of design was originally developed for qualitative research ([Maxwell, 1996](#)), and was later applied to mixed methods design ([Maxwell and Loomis, 2003](#); [Maxwell et al., 2015](#)), but without emphasizing the implications of this design strategy for integrating qualitative and quantitative methods and approaches. The integration of the qualitative and quantitative aspects of each of the design components is central to the functioning of the design, and the differences between quantitative and qualitative research make integration in mixed methods research a rather different and more complex issue than for mono-method studies. [Greene \(2007\)](#) argued that “the interaction challenge in integrated designs is under theorized and understudied ... [but] constitutes the very heart of integrative mixed methods inquiry” (p. 125). Thus, my discussion of mixed methods design will focus importantly on these differences, and on the advantages, as well as the challenges, that they create for effective integration.

In what follows, I will first briefly describe the components of this design model, and how these interact with one another (for a more detailed discussion, see [Maxwell, 2013](#)). I will then present what I see as the most important differences between quantitative and qualitative approaches, and how integrating the two creates opportunities for deeper understandings of the phenomena studied than are possible with a mono-method approach.

The components of a design

This model of research design has five components: the researcher’s goals, conceptual framework, research questions, methods (including sampling/selection, research relationships, data collection, and analysis), and validity concerns (For a much more detailed discussion of these, see [Maxwell, 2013](#), and [Maxwell and Loomis, 2003](#)).

Goals: why are you doing this study?

The researcher’s goals include not only the explicit research goals of the study, but also the practical and personal goals that these may facilitate. These goals are often implicit, in which case they may unconsciously affect the research, and it is thus important to make them explicit.

Conceptual framework: what do you already know or believe?

The conceptual framework of a study (often called the “theoretical framework”) includes all of the concepts, theories, and beliefs that the researcher holds about the phenomena, settings, and individuals to be studied. As is true for goals, these are often implicit, and need to be made explicit. However, unlike the goals, this framework is generally something that needs to be constructed in planning the study. Its sources aren’t limited to “the literature” on the specific topic or research area; it can also be drawn from

literature in other fields or through communication with other researchers, or created through “thought experiments,” and modified during the course of the study.

Research questions: what, specifically, do you want to learn?

This component, the questions that the study is explicitly designed to answer, is the “hub” of my design model, the one that most directly connects to the other components. It is usually the component that is most explicitly formulated, although these questions may evolve during the study (It is different from the interview questions, which are part of the data collection methods).

Methods: what will you actually do?

I define this component broadly, to include all of the actions planned or taken in gaining access or gathering data during the study. It consists of four main parts: the relationships created with participants, or with “gatekeepers” that control access to participants; the selection of participants, times, and settings for data collection; the actual data collection strategies; and the data analysis procedures. While these may be planned in some detail in advance, in qualitative research they are typically not fully developed before the study begins, and may be modified substantially as the research proceeds.

Validity and generalizability: how might you be wrong, and how will you address this?

This component is often treated as part of methods. However, I see the key issue as the validity threat—a way that the researcher’s conclusion might be wrong—and focus on how that threat could be assessed and dealt with, which generally includes methods but is in principle much broader than this (Maxwell, 2013, chapter 6, 2017). I also include in this component the strategies for addressing these threats, and the potential generalizability of the conclusions. Qualitative researchers usually conceptualize the latter as transferability—something that is primarily the responsibility of the reader or potential user of the results, although the researcher can facilitate this transfer by detailed description of the setting and the processes that led to the results; I discuss this in more detail below.

One aspect of a research design—ethical issues—doesn’t have a single obvious place in this model. I see it as most closely aligned with goals, but it also could fit into validity, or be seen as a separate component of the design. Ravitch and Riggan (2017) seem to implicitly include it in the conceptual framework, which they define somewhat more broadly than I do.

All of these components interact with all of the other components. In addition, particular elements of a single component interact—for example, the researcher may have multiple goals, and any of these may have consequences for other goals, as well as for elements of other components. This is particularly true for mixed methods research; the qualitative and quantitative elements of any component may differ substantially, and successfully integrating these may become a major challenge.

The following diagram illustrates the relationships among these design components. Each component interacts with all of the others; the research questions are the component that most directly connects to all of the other components (Fig. 1).

Research design and research proposals.

One of the benefits of this model of research design is that it matches a widespread structure for a research proposal. This structure typically includes the following sections:

1. Why the study is worth doing (goals)
2. What we already know or believe about the topic (conceptual framework)
3. What specific questions the study will attempt to answer (research questions; these may be stated earlier in the proposal, but need to be justified by explaining the goals and conceptual framework)
4. What settings will be studied, what relationships will these require, and what data collection and analysis strategies will be used (methods)
5. Assumptions, limitations, and potential errors in interpretation (validity)

Developing the design for a study in this way makes it easier to create a proposal for a dissertation, or for funding for the project (for a more detailed presentation, see Maxwell, 2013, Chapter 7).

The complementarity of differences

The differences between qualitative and quantitative approaches are not simply a problem to be overcome; they are also the source of important advantages in combining the two. Many of these differences are complementary; the strengths of qualitative research often compensate for the limitations of quantitative research, and vice versa (Beach, 2021). I see these complementary differences as a key issue in integrating the two approaches. In what follows, I will focus on these differences, and how combining the two approaches creates a stronger and broader result than either approach can achieve by itself. I see two primary issues for which there are major advantages in combining the two approaches: causal explanation, and generalization.

Fig. 1 Model of the relationships among research components.

Combining methods for causal explanation

I will begin with what I see as a major difference in the goals, and typical results, of the two approaches. Quantitative research is particularly good at showing *that* a particular treatment, event, or variable influenced another variable or contributed to a particular outcome. Qualitative research, in contrast, is particularly good at showing *how* a situation or event influenced another situation or event—providing an understanding of the processes that led to that outcome. For this reason, mixed methods research has important advantages in developing causal explanations of a situation or outcome.

Shadish, Cook, and Campbell, in their influential work on experimental and quasi-experimental methods (2002), stated that

the unique strength of experimentation is in describing the consequences attributable to deliberately varying a treatment. We call this **causal description**. In contrast, experiments do less well in clarifying the mechanisms through which and the conditions under which that causal relationship holds—what we call **causal explanation** (p. 9; emphasis in original).

They added that “qualitative methods provide an important avenue for discovering and exploring causal explanations” (p. 389), and described how, in one experiment, the actual cause of the result was “revealed only by the qualitative examination of the actual operation of groups” (p. 391).

This difference in the goals of the two approaches is closely connected to a difference in the view of causation associated with each approach, a part of the conceptual framework of a study’s design. Quantitative researchers often operate (implicitly or explicitly) with a positivist or “regularity” concept of causation—that causality is simply a consistent relationship between cause and effect, with nothing “behind” this that can be scientifically studied. Illari and Russo, in their book *Causality: Philosophical theory meets scientific practice* (2014), called such conceptions “difference-making” theories. These theories focus on the idea that causes make a regular, predictable difference in the things that they affect.

Qualitative researchers, in contrast, have often rejected the entire concept of causation, largely equating this with the positivist understanding of this concept. There have been two main versions of this rejection. The first of these argued that qualitative research deals with meaning and interpretation rather than causality, drawing on Max Weber’s distinction between understanding (*verstehen*) and (causal) explanation (*erklärung*). The second, and stronger, version, prominently advanced by Egon Guba and Yvonna Lincoln, was that the very concept of causation was invalid in social research: “There exist multiple, socially constructed realities ungoverned by natural laws, causal or otherwise” (Guba and Lincoln, 1989, p. 86), and “there are simply too many problems with causality to continue its use” (Lincoln and Guba, 1985, p. 159). This dispute over causation was a major feature of the so-called “paradigm wars” of the 1980s and 1990s, which polarized relationships between qualitative and quantitative researchers.

However, other qualitative researchers (e.g., Hammersley, 2012; Maxwell, 2012, chapter 3; Miles and Huberman, 1994) have accepted the legitimacy of causation, although a quite different understanding of causation from that held by most quantitative researchers. This conception emphasizes causal processes rather than regularities; it focuses on how a particular event or property of a situation affects other properties or subsequent events. This type of theory has been termed a realist, process, or mechanism theory; Illari and Russo (2014) called these “production accounts.”

The philosopher Nancy Cartwright, who has probably done the most to challenge traditional views of causation, stated that current approaches to causation

are not alternative, incompatible views about causation; they are rather views that fit different kinds of causal systems ... there is no single interesting characterizing feature of causation; hence no off-the-shelf or one-size-fits-all method for finding out about it, no "gold standard" for judging causal relations.

Cartwright (2007, p. 2).

These different conceptions of causation lead to, and draw on, different types of research questions and methods, and raise different potential validity threats to a study's conclusions. Integrating the two approaches to causation requires recognizing that each provides a major piece of a full causal explanation of some outcome or situation, and such integration is often essential to dealing with potential validity threats to that explanation.

This difference is closely connected to two types of data analysis, which I have labeled "categorizing" and "connecting" strategies (Maxwell and Miller, 2008). Categorizing strategies for analyzing data are intrinsic to quantitative analysis; data are aggregated by category (variable), allowing the researcher to identify the mean and variance of these data. Even non-numerical (nominal and ordinal measurement) data are aggregated in this way, though with different measures of central tendency and dispersion. Connections are then identified between variables; however, these provide only an aggregate measure of their association (e.g., correlation), having lost the local connections between particular events or beliefs in a specific time and context. This approach is well suited for identifying general causal patterns, consistent with a regularity understanding of causation.

Qualitative analysis, although it often employs coding of data to create categories, can also retain and analyze the unique connections among specific beliefs, actions, and events. Miles and Huberman (1984, p. 132, 1994, p. 228) used the term "local causality" for these relationships. Such local causal analysis may be essential for understanding the actual processes that led to a particular outcome. Thus, Becker (2009) argued that qualitative researchers

analyze directly observed processes, chains of events that produce the outcomes we want to understand ... Process analysis presents substantial difficulties for quantitative studies, which generally have to substitute such makeshifts as panel studies, population measurements at several selected times, etc. for realistic, more or less continuous empirical observation (p. 550).

Similarly, Goldenberg (1992), in a qualitative case study of the reading progress of two students and the effects of their teacher's behavior on this, stated that "if we see these dimensions as variables divorced from this context, we risk distorting the role that they actually play" (p. 540).

Combining methods for generalization

This difference in approaches to causation is also fundamental for generalizing causal (and other) conclusions, based on the specific individuals or settings for which data were collected. Such generalization can be either to the setting or population sampled (the "target" population), or to other populations or settings. Both of these are included in the quantitative concept of "external validity" (Cook and Campbell, 1979, p. 71; Shadish et al., 2002, pp. 53, 83–84), although Cook and Campbell clearly distinguished the two (pp. 71–73). However, these two types of generalization are quite different in the methods they require; I have labeled these "internal" and "external" generalization, respectively (Maxwell, 1992, 2017; Maxwell and Chmiel, 2014; see also Eisenhart, 2009).

Internal generalization

Internal generalization is generalization within the setting or population studied; for qualitative research, this type of generalization has been termed *petite generalization* (generalization within a case) by Erickson (1986), and *lower-order generalizability* (the generalizability of findings within the unit of analysis) by Brown-Saracino et al. (2008). Random sampling is the major quantitative strategy for internal generalization, although the "statistical significance" of such results is frequently misused or misinterpreted (Nuzzo, 2014; Amrhein et al., 2019).

Random sampling is rarely possible in qualitative studies, due to the large sample sizes required for this to be meaningful, but systematic non-random sampling can still be useful in making inferences from the individuals on whom data were collected, and the specific times and settings observed, to the larger social setting or population studied. Miles and Huberman argued that sampling broadly conceptualized (and not limited to random sampling) is a key issue for all research: "Knowing, then, that one cannot study everyone everywhere doing everything, even within a single case, how does one limit the parameters of a study?" (1984, p. 36) They stated that

you are not only sampling people, but also settings, events, and processes. It is important to line up these parameters with the research questions as well, and to consider whether your choices are doing a representative, time-efficient job of answering them (1984, p. 41).

In order to make claims about the internal generalizability of their findings, mixed methods (and qualitative) researchers need to address these issues—are the people, settings, activities, and times on which they have actually collected data adequately representative of the larger population or case that they are studying?

In addition, internal generalizability in a full sense needs to address not just whether the results capture the typical views, characteristics, or actions of the persons involved, but also the diversity of these within the case or population studied. [Ercikan \(2009\)](#) argued that quantitative studies “may use very large samples but focus on overall group results and have very little generalizability for key subgroups” (p. 211).

External generalization

Generalizing from the results for one population or setting to different populations or settings is a completely different matter. Random sampling can’t be used for this purpose, and quantitative researchers have few other tools for such generalization ([Cartwright, 2016](#)). Both quantitative and qualitative researchers have typically argued that “similarity” to the setting or population studied is the basis for generalization to other settings or populations. Shadish, Cook, and Campbell stated, as their first “principle of generalized causal inference,” that “scientists generalize by judging the apparent similarities between the things they studied and the targets of generalization” (2002, p. 353). Similarity was also invoked by Lincoln and Guba in their presentation of “transferability” (1985, pp. 124–198).

Cartwright and Hardie, in their book “Evidence-based Policy: A Practical Guide to Doing it Better” (2012), responded that

For us, the key question is how good a job this advice [similarity] does in getting you from “it worked there” to “it will work here.” The answer: you are lucky if it gets you anywhere (p. 46).

Similarity is both too vague (what features must be similar?) and too demanding (almost no two contexts are similar in all important respects), and provides no guidance in understanding how your specific context will affect the outcome of the policy (pp. 46–49).

However, the qualitative concept of “transferability” does not depend on similarity. Instead, it can draw on an understanding of the processes that resulted in the outcome in the original study, and how these processes are likely to operate in a specific new context. This approach was described in detail by Cartwright and Hardie, who emphasized the fundamental role of context in such generalization. Although they never used the term “qualitative” in presenting these issues, their book is to a substantial extent a detailed argument for the importance of qualitative methods and understandings in implementing any policy in a new context.

An essential issue in understanding these processes is meaning: the beliefs, values, and motives held by participants in the two contexts. These meanings are inherently involved in the processes involved, in both the setting studied and the new setting. As the psychologist [Bandura \(1986\)](#) argued, “What people think, believe, and feel affects how they behave. The natural and extrinsic effects of their actions, in turn, partly determine their thought patterns and affective reactions” (p. 25).

This is a second major strength of qualitative research for generalization; qualitative methods for data collection and analysis are necessary for an in-depth understanding of participants’ meanings. These meanings and processes inherently influence, and are influenced by, the context in which they occur, and qualitative methods are likewise essential for an understanding of this context and how it shapes the processes that lead to particular outcomes.

For this reason, transferability is primarily the responsibility of the reader or potential user of the original findings, who can best assess how these processes might operate in a specific new setting ([Lincoln and Guba, 1985](#), p. 298). However, the authors of the original study can facilitate such use by providing detailed information about the processes, meanings, and contexts involved in the original study.

An illustrative study

A classic mixed methods study, one that predates the coining of the term “mixed methods,” provides an example of how integrating the methods and findings of quantitative and qualitative methods and data led to a much deeper understanding than either method was able to achieve on its own. This study, an evaluation of a multi-site experimental federal housing-subsidy program, was described by [Trend \(1979\)](#) in a volume that contributed significantly to the development of mixed methods research ([Cook and Reichardt, 1979](#)).

Trend characterized the study as a “naturalistic experiment” (p. 69); it did not involve a control group. Extensive quantitative data were collected on agency activities, expenses, demographic characteristics of clients, and housing quality; survey researchers interviewed participants at scheduled interviews. In addition, each site had an observer (usually an anthropologist) who prepared a qualitative case study of that site, using field observations, interviews, and documents. The intent was that program outcomes would be determined through analysis of the quantitative data, while the case studies would provide a holistic picture of program process (Trend, p. 70).

In one site, composed of one urban and two rural subsites, the contracting agency was located 70 miles from the site, and had never been responsible for such a grass-roots program, but appeared aggressive and anxious to succeed, and intended to run a “lean

and mean" operation; few supportive services were offered. In the observer's view, the original plan never materialized. Despite delays in signing the contract, the agency was required to meet the original contract deadlines. Initial enrollment of families (which required the families to find acceptable housing) was slow in the urban site, which led the contracting agency to impose enrollment quotas and to order the curtailment of Black households, as these were overrepresented. The staff (most of whom had social service backgrounds) felt that the process was inhumane, and complained of overwork; the observer insisted that the program was hampered by managerial conflicts (with racial overtones) and incompetence, and that many families simply couldn't find acceptable housing.

However, when the quantitative outcome measures were finally reported, they showed that this site had performed quite well compared to other sites. It was demographically balanced and relatively cheap to run, and had achieved its outcome goals in terms of number of families who found acceptable housing. While neither side doubted "the facts" produced by the other, their interpretations of these facts differed radically. The agency conducting the evaluation sided with the quantitative results, and the observer was repeatedly told to rewrite his analysis to fit the quantitative conclusions.

After multiple unsuccessful attempts, Trend and the observer made a sustained effort to get at what had really been going on, using both the quantitative and qualitative data. They eventually came up with a coherent, process explanation for almost all of the data, one that went well beyond either the quantitative or the initial qualitative results, and that revealed serious shortcomings in both accounts. Separating the rural and urban subsites showed that the rural subsites were largely responsible for the positive outcome results. In addition, the fiscal requirements imposed by the granting agency had never been adequately explained to the staff at the urban subsite, leading to their frustration with the contracting agency's orders; the early departure of disgruntled employees helped lower costs (Much later, the housing quality measure used by the agency was shown to be flawed).

Trend concluded that multiple methods may not lead to an easy integration of findings, and that "unanimity may be the hallmark of work in which other avenues to explanation have been closed off prematurely" (p. 68). Had the discrepancy between the qualitative and quantitative accounts been discovered earlier, or the two approaches more closely integrated, it is possible that the observer would have been subtly or overtly coerced to make his conclusions fit the "hard" data (p. 84). Trend thus argued that "the proliferation of divergent explanations should be encouraged" (p. 68), but also that an effort be made to develop an account which does justice to all of the conflicting perspectives.

Important earlier studies that integrated qualitative and quantitative approaches, such as Blau, *The Dynamic of Bureaucracy* (1963), Festinger et al. *When Prophecy Fails* (1956), Becker et al. *Boys in White: Student Culture in Medical School* (1961), and Milgram, *Obedience to Authority* (1974), have received almost no attention in the mixed methods literature, despite being recognized as classics in their specific fields. None of these authors identified their study's design as a particular type, nor does typologizing their designs provide much useful additional understanding of what they did. Becker et al. (1961) described their design as follows:

In one sense, our study had no design. That is, we had no well-worked-out set of hypotheses to be tested, no data-gathering instruments purposely designed to secure information relevant to these hypotheses, no set of analytic procedures specified in advance. Insofar as the term "design" implies these features of elaborate prior planning, our study had none.

If we take the idea of design in a larger and looser sense, using it to identify those elements of order, system, and consistency our procedures did exhibit, our study had a design. We can say what this was by describing our original view of the problem, our theoretical and methodological commitments, and the way these affected our research and were affected by it as we proceeded (p. 17).

For a discussion of the designs of these and other early mixed methods studies, see Maxwell (2016, 2018) and Maxwell and Loomis (2003).

The study by Milgram is particularly explicit about the relative strengths of the two approaches, and how these were integrated. To understand why people might obey orders that clearly violated widely-held social values, Milgram designed an elaborate series of experiments in which participants were deceived into believing that they were part of a study of the effects of punishment on learning, and were then told to give increasingly severe (faked) "electrical shocks" to a supposed "subject" who was actually an accomplice of the researchers, and who feigned pain and eventual refusal to cooperate. The researchers employed numerous different experimental conditions designed to determine the effect of different variables on the degree of obedience (the dependent variable), and collected quantitative data about the level of shock that subjects administered (the main measure of obedience) in each of the different conditions (After publication, the study was criticized on ethical grounds).

However, Milgram also stated that

From each person in the experiment we derive one essential fact: whether he has obeyed or disobeyed. But it is foolish to see the subject only in this way. For he brings to the laboratory a full range of emotions, attitudes, and individual styles.... We need to focus on the individuals who took part in the study not only because this provides a personal dimension to the experiment but also because the quality of each person's experience gives us clues to the nature of the process of obedience (1974, p. 44).

The researchers covertly recorded the subjects' behavior during the experiment, and interviewed some subjects at length after the experiment was over to determine their reasons for compliance or refusal. The results chapters of the book combine quantitative tables and graphs with pictures of the experimental setup, observational notes, excerpts from recorded observations and interviews, and case studies of particular subjects' responses to the experimental situation, with extensive discussion of the social processes and subjective interpretations through which obedience and resistance to authority develop. And in discussing potential validity threats to the study's conclusions, Milgram used both the quantitative results from the experimental manipulations and qualitative data from the observations and interviews to rule out these threats.

Conclusions

The main lesson that I draw from these examples and analyses is that typological approaches to research design, which have dominated the self-identified "mixed methods" literature, are neither necessary, nor particularly helpful, in designing mixed methods studies. Such categories may be useful in describing a completed study, but not as a starting point for planning the study. I argue that creating a workable design needs to address the researcher's goals for the study, the conceptual framework for understanding the phenomena to be studied, the specific research questions to be answered, the methods to be used to answer these, and the potential validity threats to these answers and how these can be addressed. This is not a linear sequence; any of these components may influence any of the other components, and the design of a study needs to be an interactive and integrative process. The five components of my design model are also useful in developing a research proposal, since they cover the main issues that a proposal must address.

Integrating the quantitative and qualitative components of a design is often more challenging than in a monomethod study, but it also has important strengths for drawing conclusions. I've described two major issues for which quantitative and qualitative approaches have complementary strengths and limitations: the analysis of causation, and the facilitation of generalization. In addition, there are innumerable benefits that are specific to particular studies, as illustrated by the examples presented. In my view, the integration of methods is better facilitated by this design model than by typological conceptions of design.

Introduction

Researchers in education often strive for a detailed understanding. They want to obtain an understanding that includes various groups of students, various stakeholders, and different aspects of a phenomenon. For instance, in [Example 3](#) below, the aim is to understand the effects of providing textbooks to primary school pupils with differing pretest scores. In [Example 2](#), the aim is to understand how children, parents, teachers, and school principals in one preschool experience and evaluate the school playground. In [Example 1](#), the aim is to understand teachers' attitudes to student-centered teaching (i.e., their beliefs), their actual teaching behavior, and how the two are related.

This kind of detailed understanding is essential in order to develop educational interventions that work. Before implementing a larger-scale intervention, it is important to identify and incorporate any group differences, conflicting stakeholder views, and inconsistencies between belief and behavior. Only then will it become possible to design the optimal intervention for all concerned ([Pawson and Tilley, 1997](#)).

This chapter describes ten research strategies that can help mixed methods researchers to develop a detailed understanding of the target phenomenon ([Greene, 2007, 2015](#); [Flick, 2017](#); [Schoonenboom, 2019](#); [Uprichard and Dawney, 2019](#)). In mixed methods studies, researchers derive conclusions from qualitative and quantitative data, which they combine using a process called *integration* ([Creswell and Plano Clark, 2018](#); [De Allegri et al., 2020](#); [Tashakkori et al., 2021](#)) as in the following real-world example.

Example 1

In a study by [Assen et al. \(2016\)](#), the target group were tutors at one Dutch university, who had been appointed to facilitate and support students' learning process. This role requires a student-centered approach to teaching rather than the more traditional teacher-centered style based on "knowledge transmission":

The purpose of this study was to explore the discrepancy between teacher beliefs and behavior in a Problem-Based Learning (PBL) environment. Using a survey and observations, this study demonstrated that tutors prefer learner-oriented beliefs, but in their teacher behavior they showed a more traditional approach to teaching. Analysis of semi-structured interviews indicated that this inconsistency could be attributed to the way in which problem-based learning is embedded in the curriculum, the confidence teachers have in the self-directed capabilities of students, and the self-confidence of teachers regarding their own facilitation skills.

[Assen et al. \(2016, p. 12\)](#).

In [Example 1](#), detailed understanding emerges from learning about the participating teachers' beliefs and behaviors, the discrepancy between those beliefs and behaviors, and how that discrepancy can be explained. The explanation can be characterized as

detailed because it provides three distinct reasons for the discrepancy by exploring various aspects of the tutors' teaching approach from several perspectives and comparing and connecting those aspects.

The study referred to in [Example 1](#) is a mixed methods study because the researchers used both qualitative and quantitative methods and integrated their findings ([Creswell and Plano Clark, 2018](#); [De Allegri et al., 2020](#); [Tashakkori et al., 2021](#)). On the quantitative side, they used the survey method, asking teachers closed questions to identify their beliefs. The survey provided quantitative, numerical, and structured data, enabling the teachers' answers to be represented as numerical values in tabular form. Based on these data, the researchers could calculate the extent to which the teachers' beliefs could be characterized as "student-centered." On the qualitative side, observations of the teachers' behaviors provided unstructured video data confirming that those behaviors were more teacher-centered than their declared beliefs. To explain this discrepancy between belief and behavior, the researchers used one additional qualitative method: semi-structured interviews. The interviews yielded audio data that were then transcribed. Using qualitative thematic analysis, the derived themes were used to explain the conflict between beliefs and behaviors. Here, the mixed methods approach led to a detailed understanding by comparing the quantitative survey results with the qualitative observations to make the discrepancy between beliefs and behaviors more visible.

Choosing a mixed methods approach for your study does not automatically ensure detailed understanding any more than a mono-method approach prevents such an understanding ([Symonds and Gorard, 2010](#); [Sandelowski, 2014](#); [Flick, 2017](#); [Gobo et al., 2022](#)). To gain a detailed understanding, you will have to conduct your study sensibly. The ten strategies described here support sensible decision making in developing research that can deepen understanding through *integration* or, more precisely, *integration of claims*. As such, the ten strategies complement other advice in the mixed methods literature on integration ([Fetters et al., 2013](#); [Maxwell et al., 2015](#); [Åkerblad et al., 2021](#); [Hitchcock and Onwuegbuzie, 2022](#)); and they complement advice on strategies for other aspects of mixed methods research, such as research design ([Creamer, 2017](#); [Creswell and Plano Clark, 2018](#); [Tashakkori et al., 2021](#)), data analysis ([Bazeley, 2012, 2018](#); [Onwuegbuzie and Johnson, 2021](#)), and obtaining validity or trustworthiness ([Long, 2017](#); [Fabregues et al., 2021](#)). After briefly explaining the term *integration of claims*, the ten strategies will be described in greater detail.

Integration of claims

The process of developing a detailed understanding is referred to as *integration of claims*. In its most basic form, a claim is a statement about an entity that may be true or false. One of the claims in [Example 1](#) is *Tutors prefer learner-oriented beliefs*. This is a *simple* claim because it makes one statement (*prefer learner-oriented beliefs*) about one entity (*tutors*). Claims can also be *complex*, where there is more than one entity-statement combination, connected by a word that indicates their relationship. For instance, [Example 1](#) makes the complex claim that *Tutors prefer learner-oriented beliefs, but in their teacher behavior they show a more traditional approach*. This complex claim consists of two simple claims: *Tutors prefer learner-oriented beliefs* and *Tutors' approach to teaching is more traditional*. These two simple claims are connected by the word *but*, expressing the mismatch between tutors' preference for student-centered teaching and their teaching behavior.

Developing a detailed understanding can be viewed as a linguistic process, in which simple claims are developed and connected to form complex claims. These are in turn integrated into ever more complex claims until the most complex resulting claims can be said to provide a detailed understanding.

What is the role of methods in integration? In my view, methods are not integrated with claims, nor are they integrated among themselves. In other words, methods remain outside the "integration box" and are used to derive simple claims, as shown by the arrows from methods to simple claims in [Fig. 1](#). This differs from the view more widely held by mixed methods scholars that researchers integrate methods or data (e.g., [Bryman, 2006](#); [Fetters et al., 2013](#); [Maxwell et al., 2015](#)). I contend that the term *mixed methods* is misleading, as it is the claims rather than the methods that are mixed ([Cartwright and Hardie, 2012](#); [Cartwright, 2018](#)) or better, *integrated*.

In line with [Cartwright \(2018\)](#) and [Cartwright and Hardie \(2012\)](#), I use the word *claim* rather than *inference* here, although the latter is more common in the mixed methods literature ([Teddle and Tashakkori, 2009](#); [Creamer, 2017](#); [Tashakkori et al., 2021](#)). I do so on the grounds that *claim* and *inference*, although interchangeable in many contexts, emphasize different aspects of a statement and connote different things. For instance, characterizing the statement *Tutors prefer learner-oriented beliefs* as an inference implies that someone inferred this statement from something else—in this case, from an analysis of the survey data—so emphasizing the connection between this statement and the method *Using a survey* (see [Fig. 1](#)). By focusing on the relationships between claims, I seek to de-emphasize the connection between methods and claims, and referring to claims as *inferences* is not helpful in this regard. In addition, as we will see, researchers often introduce various claims that are not their own inferences but are borrowed from the literature, making it misleading to refer to these as *inferences*.

The word *claim* emphasizes the status of a statement as an independent entity, regardless of the methods used to derive it. This is important when considering the issue of validity, which is a property of claims and not of methods; even correctly applied methods can produce a claim that is false ([Maxwell, 2013](#)). *Claim* also has another connotation that *inference* tends to underplay: the possibility of being false. A Google search (January 9th, 2022) returned many more hits for *false/invalid claim* (26,700,000) than for *true/valid claim* (1,570,000), but this ratio was reversed for the far less frequent term *inference*; *true/valid inference* returned 68,200 hits while *false/invalid inference* returned 51,500 hits. By implication, *claim* is much more strongly associated than *inference* with *possibly false*.

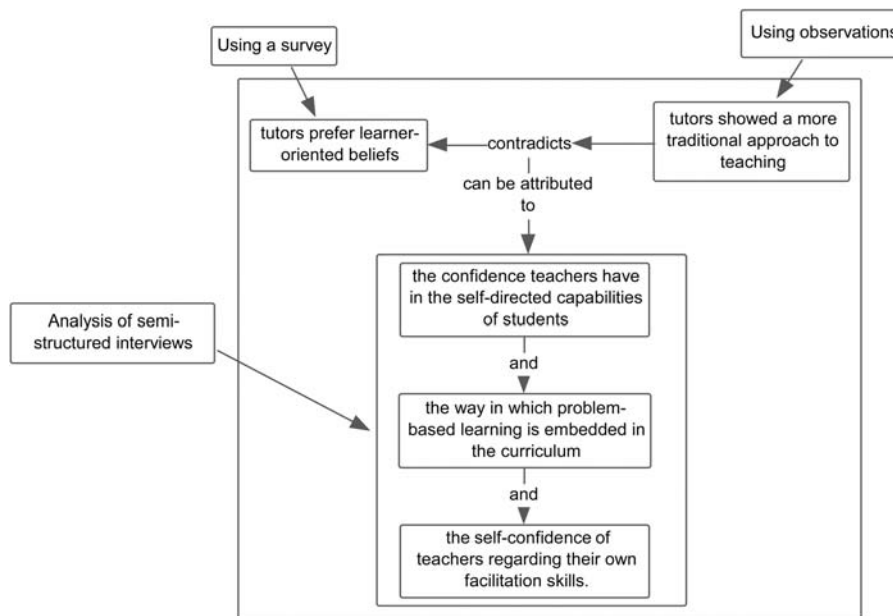

Fig. 1 Integration of claims in mixed methods research.

Taken together, these arguments point to different user expectations regarding the terms *claim* and *inference*. When I use the correct methods to *infer* something from my data, I do not expect the resulting inference to be false. In contrast, a derived claim—as an entity that has become independent from its methods—could possibly be false, given the strong connection between *claim* and *being false*. As mixed methods research pursues detailed understanding, it is important to be constantly reminded that our claims may be false, prompting further investigation. For that reason, I favor the term *claim* in the present context.

When researchers integrate claims in language, they do not necessarily “integrate” previously separate or “disintegrated” events or circumstances into one coherent whole. On the contrary, the integration underpinning the complex claim *Tutors prefer learner-oriented beliefs, but in their teacher behavior they showed a more traditional approach to teaching* in fact disintegrates a reality. Each of these simple claims describes a coherent reality, but together they create a disintegrated reality that contains an inherent contradiction (indicated by the word *but*). Thus, a linguistic integration can create either empirical coherence or empirical incoherence—an empirical “integration” or an empirical “diffraction” (Uprichard and Dawney, 2019). We could also characterize this process as *developing theory*: theory that consists of connected and integrated, simple claims and that stays close to the data from which it had been developed.

The integration process is summarized in Table 1 (Example 1).

As Table 1 shows, integration does not occur by combining simple claims into one complex claim all at once. Instead, the process of mixed methods research includes successive *integration points* (Guest, 2013); at each such point, two or more claims are brought together and linked by words like *but*, *and*, or *because*. In Table 1, at integration point I, the two simple claims [1] and [2] are brought together and connected by the word *but*, indicating that they are contradictory.

Each integration point is labeled to indicate its *integration type*; for example, integration point I is labeled *mixed methods* because it connects claims derived from quantitative surveys and qualitative observation. Integration point II is labeled *mono-method* because it integrates claims derived from one method only (semi-structured interviews). These different types of integration point serve to explain why Example 1 is a mixed methods study: because it contains at least one mixed methods integration point, in this case two (points I and III). In addition, these types explain why claim integration is not confined to mixed methods research (Symonds and Gorard, 2010; Sandelowski, 2014; Flick, 2017; Gobo et al., 2022). For example, even if the researchers in Example 1 had only conducted semi-structured interviews, they would still be able to develop and integrate claims using mono-method integration points like II. Thus, in a mono-method study too, claims can be developed and integrated to obtain a detailed understanding. In addition, claims can be developed and integrated using only different quantitative or only different qualitative methods (e.g., interviews and observations). Such integration is performed in *multi-method* integration points. We will meet two further types of integration point types later in the section *Consider various types of integration*.

The last and most complex integration point in a mixed methods study is the *meta-inference* (Teddlie and Tashakkori, 2009; Creamer, 2017; Tashakkori et al., 2021; Schoonenboom, 2022). *Meta* (Greek: beyond) refers to an inference “beyond” both quantitative and qualitative claims. The meta-inference, then, can be regarded as the study’s theory, when we reach a detailed understanding by connecting several claims in a way that makes sense. Often (though not always), the meta-inference resolves a contradiction by providing an explanation. In Example 1, there was a conflict between claims based on the survey and those based

Table 1 Integrating claims in Example 1.

Obtaining claims		Integrating claims	
Methods	Claims	Integrated claims	Connection
I. Mixed methods			
Survey	→ [1] Tutors prefer learner-oriented beliefs.	IC [3] Tutors prefer learner-oriented beliefs, but they show a more traditional approach to teaching.	Contradiction
Observations	→ [2] Tutors show a more traditional approach to teaching.		
II. Mono-method (qualitative)			
Semi-structured interviews	→ [4] Problem-based learning is embedded in the curriculum in a specific way.	IC [7] Problem-based learning is embedded in the curriculum in a specific way, and teachers have a certain amount of confidence in the self-directed capabilities of students and showed varying amounts of self-confidence regarding their own facilitation skills.	Juxtaposition
	→ [5] Teachers have a certain amount of confidence in the self-directed capabilities of students.		
	→ [6] Teachers showed varying amounts of self-confidence regarding their own facilitation skills.		
III. Mixed methods			
Survey & observations	→ IC [3] Tutors prefer learner-oriented beliefs, but they show a more traditional approach to teaching.	IC [8] Tutors prefer learner-oriented beliefs, but they show a more traditional approach to teaching because problem-based learning is embedded in the curriculum in a specific way and teachers have a certain amount of confidence in the self-directed capabilities of students and showed varying amounts of self-confidence regarding their own facilitation skills.	Explanation
Semi-structured interviews	→ IC [7] Problem-based learning is embedded in the curriculum in a specific way and teachers have a certain amount of confidence in the self-directed capabilities of students and showed varying amounts of self-confidence regarding their own facilitation skills.		

Note. IC = integrated claim.

(Eds.), *The Routledge Handbook for Advancing Integration in Mixed Methods Research*, Routledge, p. 58, <https://doi.org/10.4324/9780429432828-6>. CC BY-NC-ND 4.0.

on the observations. In the meta-inference, the researchers resolved this contradiction by developing an explanation based on the claims from the interviews: that tutors' actions differed from their beliefs *because* of how their course was embedded in the curriculum and because of their estimation of their own skills and those of their students. In some mixed methods studies, however, a meta-inference creates a contradiction rather than resolving one (see Example 2 below).

Ten integration strategies for mixed methods research

Strategies for integrating claims form part of the mixed methods research process. Fig. 2 is based on a standard representation of that process (Ivankova et al., 2006; Morse and Niehaus, 2009; Teddlie and Tashakkori, 2009; Creswell and Plano Clark, 2018); (for an alternative representation, see Maxwell, 2013). According to this standard model, the study's goal and purpose guide all research activities, including data collection and analysis, deriving conclusions, and integrating qualitative and quantitative conclusions into a single meta-inference. There are three possible paths: collecting and analyzing qualitative and quantitative data at the same time (path a); collecting and analyzing quantitative data after qualitative data (path b); or collecting and analyzing qualitative data after quantitative data (path c).

The initial steps of the proposed alternative model (Fig. 3) are not dissimilar to the standard model of mixed methods research, in that the goal and research questions are used to plan the study. However, the proposed model is not confined to mixed methods research. A range of data sets is still collected and analyzed, but, as outlined in the Introduction, these data sets may include quantitative and qualitative data, qualitative data only, or quantitative data only, from which simple claims are derived. Fig. 3 represents only the first part of a study, ending at the first integration point; the result is not a meta-inference but a first integrated claim.

Beyond this first integrated claim, the research process continues to *Reflect on next step*, which is where the proposed model begins to deviate from the standard model (see Fig. 4). This reflection often creates backward loops, as the result typically involves taking a few backward steps in the research process. In Example 1, for instance, the researchers discovered a contradiction at integration point I (*Tutors prefer learner-oriented beliefs, but in their teacher behavior they show a more traditional approach*). The researchers' next step was to look for an explanation by re-analyzing the interviews; this step is indicated in Fig. 4 as a back arrow from *At each integration point, reflect on the next step* to *Search for explanation*, followed by integration of the contradiction and the explanation (path ex. 1).

Fig. 2 A standard presentation of the mixed methods research process.

These backward loops have important implications for the process of mixed methods research. Mixed methods studies are guided by the research goal and research questions (Bryman, 2007; Ridenour and Newman, 2008; Teddlie and Tashakkori, 2009; Bazeley, 2018) and by each integration point. That is, the decision at each integration point may change the study's goal and research questions, and consequently the research plan. As shown in Fig. 4, *Adjust goal*, *Develop new research questions* and *Re-plan the study* are possible research activities, all steered by an integration point.

Fig. 4 also shows that integration points steer and initiate several integration strategies. For example, *Finding an explanation* becomes relevant as a next step only after *integrating claims* reveals a contradiction. Not all integration strategies assume previous integration (e.g., *Search for contradiction*), but other strategies typically arise after performing a first integration step (e.g., *Analyze subgroups*, *Search for an explanation*).

Of the 17 research activities or strategies in Fig. 4, this chapter discusses 10 (presented in *italics*). I selected these ten strategies because they relate directly to integration and because they seem most useful for developing a detailed understanding. Nine of these ten strategies relate to the integration of claims; the exception is *Integrate data sets where possible* (which obviously relates to data integration). Where relevant, I briefly discuss other research activities and strategies shown in Fig. 4.

Strategy 1: incorporate the perspectives of all relevant stakeholders

As claims can be integrated only if they exist, mixed methods researchers should include diverse perspectives on the target phenomenon at various levels of the research process (Greene, 2006; Mertens, 2007; Flick, 2017). The resulting data sets can be used to derive claims that may sometimes be contradictory. Elsewhere, I refer to this process as *diversification* (see Johnson (2017) and Johnson and Schoonenboom (2016) for extended lists of diversification strategies). Below, I discuss the two most important forms of diversification in mixed methods research: *including perspectives of various stakeholders* and *developing a range of data sets* (see Fig. 4). Example 2 illustrates the use of *including various stakeholder perspectives* in a mixed methods study.

Fig. 3 Initial steps of proposed model of claim integration (to first integration point).

Example 2

A study by Clark and Moss (Clark, 2005, p. 14)

was a collaboration with Learning through Landscapes, a charity based in England that works to promote the use, development and maintenance of school playgrounds. [...] The study was based in a preschool for three- to four-year-olds. Twenty-eight children were involved, together with parents and practitioners. [...] The manager, practitioners and a group of parents wanted to take more advantage of the small outdoor space available to the preschool. This included a soft play surface, a small area of decking, a muddy bank and “boggy” ground where there was an underground spring.

According to Clark (2005, p. 16),

Observing the children revealed the house to be a key resource for them. The children confirmed this through their photographs, the tour, and their interviews. Parents also mentioned the house as an important space in the preschool. However, the interviews with practitioners showed that the house was a source of tension. They felt it was too small. The review with children, practitioners, and Learning through Landscapes recognised these opposing views and raised some possible solutions. The preschool has now turfed a new area for children to use to build their own temporary structures.

Here, the researchers collated the various claims of different stakeholders, including children, parents, practitioners, school principals, and Learning through Landscapes (the organization responsible for redeveloping the playground). Analysis of the interviews showed that some of these claims were contradictory, as practitioners differed from children and parents in their view of the playhouse, and this influenced the decision regarding further development of the playground. The study highlights the essential role of differing stakeholder perspectives (especially those of practitioners) in developing the playground in the best possible way.

Strategy 2: develop a range of data sets

Mixed methods researchers develop at least one quantitative and one qualitative data set, each providing a unique perspective on the target phenomenon. Researchers can build data sets by collecting primary data, using existing data sets, or transforming

Fig. 4 Light bulb model of mixed methods integration with feedback loop. *Note.* **ex. 1** = **Example 1**. Strategies in *italics* are discussed in this article.

qualitative data into quantitative data in a process called *quantitizing* (Sandelowski et al., 2009; Bazeley, 2018; Nzabonimpa, 2018; Onwuegbuzie and Leech, 2019). The range of data sets in **Example 1** include a survey of tutors' beliefs about teaching, observations of tutors' behavior, and interviews. In **Example 2**, the data sets are even more varied, including photographs taken by the participating children, observations of children playing, reports of tours organized by children, and interviews with a range of stakeholders.

Strategy 3: integrate claims step by step

In a mixed methods study, claims are integrated step by step rather than all at once (De Allegri et al., 2020; Schoonenboom, 2022). In **Example 1** (see Table 1), separate claims were derived from a questionnaire, observations, and interviews. As a first integration step, the researchers identified a contradiction between claims based on the questionnaires and the observations: *Tutors preferred student-centered teaching, but their behavior was teacher-centered*. In a second step, they integrated the simple claims derived from the interviews. In a third and final integration step, they resolved the contradiction by deriving an explanation from the integrated interview claims.

Claims were also integrated step by step in [Example 2](#). The first step integrated claims from observations, children's photographs, tours, and interviews with children and parents confirming that the playhouse was an essential resource for the children. The second and final integration step identified a contradiction between these positive claims and the views of practitioners, who regarded the playhouse as a source of tension.

Strategy 4: consider various types of integration

Mixed methods researchers perform various types of integration; for instance, [Example 1](#) includes one mono-method and two mixed methods integration points (see [Table 1](#)). Another type is the multi-method integration point, which integrates claims derived from two qualitative methods or two quantitative methods. [Example 3](#) illustrates two further types of integration point.

Example 3

[Glewwe et al. \(2009\)](#) studied the effects of providing textbooks to primary school children in rural Kenya in schools where textbooks had not previously been used. The study started by comparing children's subject test scores in 50 intervention schools and 50 control schools. Next, in each intervention class, one child with a median score was asked to read aloud from their textbook and to answer some questions. Finally, the test scores of children with high pretest scores and other students were separately analyzed to determine whether providing textbooks had any identifiable effect:

A randomized evaluation in rural Kenya finds, contrary to the previous literature, that providing textbooks did not raise average test scores. Textbooks did increase the scores of the best students (those with high pretest scores) but had little effect on other students. Textbooks are written in English, most students' third language, and many students could not use them effectively.

[Glewwe et al. \(2009, p. 112\)](#).

[Example 3](#) is again a mixed methods study. In this case, researchers developed and integrated claims from test scores (quantitative data) and observations (qualitative data), but they also developed two integrated claims without referring to empirical data. Instead, they found that a claim from previous research (that *providing textbooks affects test scores*) contradicted their own finding (that *providing textbooks does not affect test scores*). This approach can be characterized as *Integration with previous research*.

Finally, the researchers in [Example 3](#) developed a claim on the basis of reasoning only—that is, without empirical verification—that *students with the highest pretest scores were able to read their textbooks*. Their reasoning was as follows. If providing textbooks had an effect among students with the highest pretest scores, these students must have been able to read their textbooks, which could not otherwise have had any effect, as the results for students with lower pretest scores suggested. Integration of the theoretically derived claim (that *students with the highest pretest scores were able to read their textbooks*) and the empirically derived claims about the other students can be characterized as *Integration with theoretically derived claims*.

Strategy 5: use each integration point to reflect on the next step

The primary strategy of mixed methods research can be described as follows: *Mixed methods researchers should reflect on their next step at each integration point*. In [Example 1](#), at integration point 1, the researchers identified a contradiction and decided to search their interviews for an explanation. In the absence of any such contradiction, they would probably have adopted a different perspective when analyzing the interviews.

In [Example 2](#), the crucial integration point is the point at which the positive opinions of children and parents are integrated with the practitioners' critique. Here again, a contradiction emerges. Instead of further claim integration, this contradiction steered the measures taken to develop the playground. To address the issue of playhouse overpopulation, the designers created a new area where the children could build their own temporary structures.

In [Example 3](#), a contradiction arose when integrating the claim from the quantitative study (*Providing textbooks had no effect*) with the claim from previous research (*Providing textbooks has an effect*). Reflecting on this contradiction prompted the researchers to search for an explanation by observing children, and they found that *most children were unable to read their textbooks*. Having established that textbooks had an effect on students with higher pretest scores, a second contradiction arose. In this instance, the researchers used reflection to arrive at an explanation: that *students with high pretest scores could read their textbooks*.

Strategy 6: integrate qualitative and quantitative data into a single data set

This strategy involves integrating data rather than claims. While qualitative and quantitative data can be visually integrated by presenting them side by side in a *joint display* ([Guetterman et al., 2015a,b](#); [Plano Clark and Sanders, 2015](#)), Strategy 6 goes one step further by bringing qualitative and quantitative data together in a new integrated data set. It is important to note that the mixed methods literature often uses the term "data integration" to refer to the use of different data sets in a mixed methods study ("integration within a study") without integration of the data sets themselves ([Irwin, 2008](#); [Fetters et al., 2013](#); [Maxwell et al., 2015](#)). In

Table 2 Reconstructed case comparison table of the data in Lee and Greene (2007).

ID	C	GPA	Quotation
0607	4	4.00	I do not have any language problems.
2020	3	4.00	I understand 80% of the lectures. Careful reading complements 20% of lack of understanding.
1315	3	4.00	My biggest problem is related with speaking in English. I will get a good grade because my mathematical background is strong.
0609	3	4.00	The professor is old so that his pronunciation is not clear. He usually handed out important contents and I could understand it by reading the textbook.
0620	2	4.00	I understand only 60–70% of the lectures. It has made my scores less than my expectation.
1310	3	3.89	I want to participate and argue the subject. But I cannot find myself enough. This does not affect my grade.
0624	2	3.80	It is easy to understand the lectures and participate in class discussions. The instructor speaks slowly.
2036	3	3.57	The major problem is speaking. I spoke once or twice during the whole semester.
0610	3	3.53	Listening is a problem. Lack of cultural knowledge interferes with understanding the concept.
0605	2	3.50	Because of my poor listening, I am struggling with catching up with my content courses.
0603	3	3.39	I still have some problem in speaking. This difficulty doesn't affect my ability to do well in all the courses I take.
2037	2	3.22	Lack of knowledge about idiomatic expressions prevents me from understanding questions on the homework assignment.
2025	3	3.18	I was not able to finish all the reading assignments every week.
2031	3	3.11	I have problems with my hearing and how to speak correctly.
0608	4	2.89	I understand almost 100% of the lectures. I understand the professor completely. [...] grades are not important. That is the least of my worries. [...]

ID = student ID; C = CEEPT score; GPA = student GPA; Quotation = utterance by student.

Adapted with permission from Schoonenboom, J., Johnson, R.B., 2021. The case comparison table: a joint display for constructing and sorting simple tables as mixed analysis. In: Onwuegbuzie, A.J., Johnson, R.B. (Eds.), *The Routledge Reviewer's Guide to Mixed Methods Analysis*, Routledge, p. 278, <https://doi.org/10.4324/9780203729434-24>. CC BY-NC-ND 4.0.

contrast, the term *data integration* will be used here only when two data sets are integrated into one data set that contains both qualitative and quantitative data.

An integrated data set can be represented as a *case comparison table* (Schoonenboom and Johnson, 2021), as in **Example 4**.

Example 4

In a study of international graduate students at a large public university in the United States, Lee and Greene (2007) “investigated the relationships between graduate students’ placement test scores for English as a second language (ESL) and three measures of academic performance (grade point average [GPA], faculty evaluations, and student self-assessments)” (Lee and Greene, 2007, p. 366). In addition to Computerized Enhanced ESL Placement Test (CEEPT) scores and students’ GPA, qualitative data were obtained by interviewing 20 students. I re-analyzed the available data from the published article, and the results are presented below (Table 2) as a case comparison table (Schoonenboom and Johnson, 2021).

In a case comparison table, researchers use quantitative data to group and sort qualitative quotations until patterns begin to emerge. Table 2 includes qualitative and quantitative data for each student. The CEEPT and GPA scores are quantitative data, enabling us to count occurrences of individual values and to calculate means and standard deviations. The quotations are qualitative data; it would not make sense to count the number of occurrences of each quotation (which would be 1).

Table 2 shows that some students with an imperfect command of the English language nevertheless attained the highest possible GPA score. The four students with a CEEPT score of less than 4 and a GPA score of 4 are shown in bold. In their quotations, three of these students refer to strategies that compensate for their language problems: careful reading (ID 2020), a strong mathematical background (ID 1315), and reading the textbook (ID 0609). As none of these compensation strategies was mentioned by any of the less successful students, this formed the basis for my meta-inference and preliminary hypothesis: *Language problems affected students’ grade point average at one US university, with the exception of students who developed compensation strategies*.

Strategy 7: search for contradictions

Mixed methods researchers should search actively for contradictions (Greene, 2006; Johnson and Schoonenboom, 2016; Uprichard and Dawney, 2019) throughout the research process by comparing the claims derived from different data sets (e.g., **Example 1**: *Tutors prefer learner-oriented beliefs, but their approach to teaching is more traditional*). Researchers should also look for contradictions between study outcomes and previous research (e.g., **Example 3**: *Providing textbooks increased quantitative test scores elsewhere but not in Kenya*). A study may include more than one contradiction (e.g., **Example 3**: *Providing textbooks increased quantitative test scores among students with the highest pretest scores but not for others*). A second contradiction is often a refinement of the first (in this case, *Providing textbooks did not increase test scores*).

Where a contradiction emerges, researchers can deploy various strategies to resolve it by looking for an explanation (see **Fig. 4**)—for instance, by referring to the curriculum and teachers' estimations of their own capabilities and those of their students (**Example 1**); to differences in reading ability between students with high pretest scores and others (**Example 3**); and to differences between students who use language compensation strategies and those who do not (**Example 4**).

A contradiction can also be the outcome rather than the driver of a mixed methods study (Uprichard and Dawney, 2019), where the contradiction is not resolved but is used in a productive way. In **Example 2**, for instance, children and parents valued the playhouse, but practitioners felt it was a source of tension because it was too small. As the researchers did not explain this difference of opinion, the contradiction was unresolved. Instead, the designers used it to make a practical decision: "The review with children, practitioners, and Learning through Landscapes recognized these opposing views and raised some possible solutions. The preschool has now turfed a new area for children to use to build their own temporary structures" (Clark, 2005, p. 16).

Finally, the proposed light bulb model of mixed methods integration includes a strategy that complements the search for contradictions: *Searching for confirmation* (see **Fig. 4**), which was once considered the most important reason for conducting multi-method or mixed methods research (Campbell and Fiske, 1959; Denzin, 1978; Flick, 2017). For instance, in **Example 2**, the interviews with parents confirmed the children's view that the playhouse is an important resource for them. Today, searching for contradictions is considered more important (Greene, 2015; Johnson and Schoonenboom, 2016; Johnson, 2017), as this can lead to new insights (as the examples show).

Strategy 8: revisit and re-analyze the data

Mixed methods research is a step-by-step process. Researchers step forward by integrating and developing their claims, but they also step back. In a mixed methods study, researchers return to data already collected and analyzed and re-analyze those data to deepen understanding. By repeating this strategy wherever possible, researchers obtain an understanding that is as detailed as possible, given the data they had collected (Creswell and Plano Clark, 2018, Chapter 9).

In all four examples (most notably Examples 3 and 4), the researchers re-analyzed their data. In **Example 3**, analysis of the quantitative data had previously indicated that providing textbooks did not affect quantitative test scores because most children could not read their textbooks. However, the re-analysis revealed two distinct effects for two different groups; unlike most children, those with high pretest scores benefited from the textbooks because they could read them. In **Example 4**, I re-analyzed Lee and Greene's qualitative and quantitative data and used a case comparison table to develop a tentative hypothesis: *Some students with an imperfect command of the English language attained the highest possible GPA because they used compensation strategies*.

Strategy 9: analyze subgroups

Mixed methods researchers should search for subgroups and seek to identify any contradictions between them. Subgroup analysis often, but not always, involves re-analyzing parts of a data set previously treated as a single whole, as a special form of Strategy 8 (*Re-analyze the data*). However, subgroup analysis warrants discussion in its own right as an important integration strategy in mixed methods research.

In Examples 3 and 4, the researchers used this approach to explain the differences between subgroups. In **Example 3**, there were two subgroups: students with high pretest scores and all other students. In **Example 4**, the subgroups were students with language problems who attained the highest possible GPA and students with language problems and lower GPA scores. In quantitative research, this form of explanation involves a *moderating factor*, which prevents an adverse effect from occurring or facilitates a positive effect (Hayes, 2017). In **Example 3**, reading ability is a moderating factor because it explains why textbooks affect quantitative test scores. In **Example 4** the moderating factor is compensating strategies that mitigate the negative influence of language problems on GPA. In summary, mixed methods researchers should analyze subgroups and look for differences and moderating factors that might explain these differences.

Strategy 10: plan and re-plan the study

In the light bulb model, the steering effect of integration points has important implications for mixed methods design. The first steps of a mixed methods study can be planned using the standard model: developing an overall goal and an initial research question, collecting and analyzing a range of data sets, and deriving simple claims (see **Fig. 3**). After the first integration step, however, integration points begin to shape how the study should proceed. This means that researchers cannot plan all of their research activities at

the outset because the outcome of the first integration step cannot be known in advance. As the integration points guide further action and prompt re-analysis of the data or collection of additional data, initial planning is necessarily followed by re-planning at various points throughout a mixed methods study.

This re-planning is apparent in the examples presented here. In **Example 4**, re-analysis of the data in [Lee and Greene \(2007\)](#) was planned long after the authors had completed the original study. In **Example 1**, the researchers based their interviews on questionnaire data ([Assen et al., 2016](#)), designing the interview guidelines after the questionnaire data highlighted a contradiction: *Tutors prefer learner-oriented beliefs, but in their teacher behavior they show a more traditional approach*. This contradiction prompted the interviewers to search for an explanation. In **Example 3**, [Glewwe et al. \(2009\)](#) conducted classroom observations after identifying a first contradiction: *Providing textbooks raises test scores of primary school pupils elsewhere but not in rural Kenya*. This finding shaped the design of their observations, which sought to explain why providing textbooks appeared to have no effect.

Integration points do not fully determine the course of a study, as researchers can to some extent preplan what they will do after the first integration point. In the studies referred to here, researchers may have planned to conduct interviews (**Example 1**) or observations (**Example 4**) at the outset. However, the direction of these interviews and observations could not be planned until the researchers had performed their first integration step, which in this case revealed a contradiction. They may instead have decided to conduct the interviews and observations only after discovering a contradiction, although this is not clear from the published accounts. In any event, the researchers in Examples 1 and 4 could not continue *exactly* as planned after their first integration point because they had to explain a contradiction that was unknown at the beginning of the study. As a result, both studies necessarily involved feedback loops (see [Fig. 4](#)).

Conclusion

To gain a detailed understanding of the target phenomenon, mixed methods researchers proceed step by step, deriving claims from quantitative and qualitative data and then integrating those claims. In this chapter, I have highlighted ten strategies for integrating claims and data in mixed methods studies.

- Strategy 1: Include the perspectives of all relevant stakeholders
- Strategy 2: Develop a range of data sets
- Strategy 3: Integrate claims step by step
- Strategy 4: Consider various types of integration
- Strategy 5: Use each integration point to reflect on the next step
- Strategy 6: Integrate qualitative and quantitative data into a single data set
- Strategy 7: Search for contradictions
- Strategy 8: Revisit and re-analyze the data
- Strategy 9: Analyze subgroups
- Strategy 10: Plan and re-plan the study

According to the light bulb model of mixed methods integration ([Fig. 4](#)), these strategies are not mere guidelines or options but together optimize and deepen understanding by integrating different phases of the research process: conceptualization (*Include various perspectives*); data collection (*Develop a range a range of data sets; Integrate data sets where possible*); data analysis (*Analyze subgroups; Revisit and re-analyze the data*); integration (*Integrate claims step by step; Search for contradictions; Consider various types of integration*); and planning (*Reflect on the next step; Plan and re-plan the study*).

More importantly, these strategies can be used together because they build on each other. For example, integrated data sets can be used to perform subgroup analysis. If subgroup analysis reveals a contradiction, an explanation may be found by re-analyzing existing data or collecting new data. The process as a whole encompasses five integration strategies and may constitute only a small part of a larger study, which may in turn involve the use of many additional integration strategies.

We have known for some time that mixed methods research is emergent ([Poth, 2018; De Allegri et al., 2020](#)); in other words, the meta-inference is not developed at the end by incorporating and connecting the derived claims in a single move. The light bulb model fully acknowledges this emergent quality by incorporating points of integration that guide the research process. In practice, this means that one cannot and should not wait until data collection and analysis are complete before starting to develop the meta-inference.

A further implication for practice is that preplanning of a mixed methods study is necessarily limited because there is no way of anticipating where the first integration point will lead. It is important to plan your study as far as possible, and here the standard model ([Fig. 3](#)) can be helpful. It is, however, equally important to accept that you can never proceed exactly as planned, as you cannot know in advance what your findings will be or what claims will emerge, and for that reason, you cannot predict the outcome of your first integration step. This integrated claim will guide the next step of the research process, and any emergent contradictions can only be identified and resolved after integrating your claims.

Introduction

In this chapter, convergence and divergence in mixed methods (MM) research derives from the integration of qualitative (QUAL) and quantitative (QUAN) methods. They can be made explicit (guided by a cognitive representation of the outcomes to be created) and reported in scientific publications. In accordance with [Greene \(2007\)](#), the authors “acknowledge and respect the value of divergence as generative of unanticipated insights and understandings” in MM research (p. 152). Convergence and divergence presented in this chapter refer to the integration of QUAL and QUAN methods at three dimensions: scientific paradigms and worldviews, mixed studies reviews, and data collection and analysis in primary research.

In the MM literature, seven dimensions of integration are commonly mentioned: (a) scientific paradigms, e.g., MM research team members’ scientific worldviews can be different and mixed; (b) literature reviews, e.g., mixed studies reviews include qualitative, quantitative and MM studies; (c) theories or conceptual frameworks; (d) methodologies; (e) research questions or objectives; (f) designs; and (g) data collection/analysis techniques ([Creswell and Plano Clark, 2018](#); [Pluye and Hong, 2014](#); [Tashakkori and Teddlie, 2010](#); [Johnson et al., 2007](#); [Fetters, 2020](#); [Pluye et al., 2022](#); [Hong et al., 2017](#)). MM must, at a minimum, integrate QUAL and QUAN methods through the research questions, the research design, and the data collection/analysis. Stated otherwise, the quality of MM studies that integrate QUAL and QUAN methods at all six dimensions are not necessarily better than those that integrate QUAL and QUAN methods involving at least three dimensions (question, design, and data collection/analysis).

MM integrate QUAL and QUAN methods in both empirical research and program evaluation ([Creswell and Plano Clark, 2018](#); [Tashakkori and Teddlie, 2010](#)). For example, MM allows for the development of practice-specific knowledge and training for medical education researchers, graduate students, and professionals ([Schifferdecker and Reed, 2009](#)). MM help to answer questions about the effectiveness of interventions and programs, the processes behind them, and the stakeholders’ experiences and perspectives on phenomena under study ([Pluye and Hong, 2014](#)). In this chapter, MM empirical research meets three conditions: (a) at least one QUAL method and one QUAN method are combined; (b) each method is used in a rigorous manner according to generally accepted criteria of the methodology or research tradition invoked; and (c) the methods are integrated at least through research question(s)/objectives(s), the MM design (be it planned or emergent), and the evidence ([Pluye and Hong, 2014](#); [Johnson et al., 2007](#); [Fetters, 2020](#); [Creswell and Plano Clark, 2018](#); [Tashakkori and Teddlie, 2010](#)). As mentioned by [Ivankova \(2015\)](#): “Stated simply, there is no true MM study without methods integration or mixing” (p. 21).

The purpose of this chapter is to provide students, teachers and researchers in education and related areas an analytical argument on the concepts of convergence and divergence in MM research. These concepts will be defined and illustrated using MM reference textbooks and articles, and MM education-related empirical studies. In the following section, they will be discussed in three dimensions: MM researchers’ scientific worldviews, mixed studies reviews, and MM primary research. This order has been chosen because worldviews influence reviews and primary research, and reviews influence primary research.

Convergence and divergence of scientific worldviews

MM research casts new light on the use of researchers' differing personal worldviews because researchers may experience worldview-related interpersonal tensions when working in MM teams (Mertens et al., 2016). While some tensions can be creative and constructive, worldview stereotypes and stigmatization can be very disruptive, especially for students (e.g., in thesis committee meetings). These challenges are rarely reported in MM publications, and few MM reference texts address how to handle worldview-related tensions and how to combine worldviews. The scarcity of solutions testifies to the need to provide comprehensive guidance for how to combine worldviews in MM research when doing so is constructive and desirable.

Thus, the purpose of this section is to propose a comprehensive understanding of the combinations of worldviews in MM research, which represent the convergence and divergence of MM research teams' worldviews. These combinations suggest recommendations to prevent and manage worldview-related tensions, and a decision tree for students to combine worldviews in MM projects. These recommendations can be especially useful in education where students and researchers use a variety of QUAL and QUAN methods, and adhere to a variety of worldviews.

Problem

In this chapter, worldviews are defined as individual sets of philosophical assumptions or beliefs that guide actions. Thus, combining worldviews means supporting the perspective or mental model of each member of MM research team or thesis committee (mental models used to read and interpret MM protocols, publications and studies). In contrast to the community-level concept of paradigm, which reflects the shared commitment of a community of scientists to a set of logics, models and exemplars (Kuhn, 1983; Hacking, 1981), the individual-level term worldview indicates that the focus is on one person's view of the world and sciences, which usually mirrors paradigms. As stated by Denzin (2010), "paradigms are human constructions, and define the shifting worldview of the researcher-as-bricoleur" (p. 421). When working in MM teams, each researcher's worldview reflects their preferred paradigm (consciously or unconsciously).

Multiple MM scholars claimed the pluralism of paradigms and related worldviews in MM research (Ghiara, 2020; Niglas, 2010; Teddlie and Tashakkori, 2003), and mentioned that team members' worldviews can be combined in a MM empirical studies (Ghiara, 2020; Wenger-Trayner et al., 2019; Harvey et al., 2020; Fàbregues et al., 2021). Typically, scientific paradigms and researchers' worldviews are underreported in MM studies (Greene, 2007; Coates, 2021; Alise and Teddlie, 2010), but that does not mean that they are ignored. It could simply mean that other things are considered more critical to include within the allotted word limit of scientific publications. In addition, some MM students and researchers may be unsure about their personal worldviews as one's worldview can evolve over time, especially during one's doctoral training (Baumard, 1997), and silence their uncertainties.

However, little MM reference texts address how to handle worldview-related tensions and combine worldviews beyond the dialectical approach and pragmatism (Johnson, 2017; Hesse-Biber, 2015). The absence of guidance on how to select a combination of worldviews is problematic (Pascal et al., 2018). Typically, reference texts provide a detailed example of how to perform only one combination (Ghiara, 2020; Harvey et al., 2020; Martel et al., 2021; McChesney and Aldridge, 2019; Schoonenboom, 2019; Wenger-Trayner et al., 2019) such as combining pragmatism and constructivism in a dialectical manner (performative paradigm) (Schoonenboom, 2019), whereas multiple combinations are possible.

Common worldviews and their combinations

In previous work (Pluye et al., 2022), a literature review identified and described five prevailing scientific contemporary worldviews in MM research: postpositivism, social constructivism, pragmatism, critical theory, and critical realism. Then, six possible combinations of worldviews were determined (a-paradigmatic, substantive theory, single worldview, multiple worldviews, complementary strengths, and dialectical pluralism). This does not imply that using different worldviews in the same study ensures their combination, nor that integration of worldviews is necessary, desirable, or better than no integration. It depends on the context of the study. Furthermore, one's worldview does not equate to one's choice of QUAL or QUAN or mixed methods; worldviews can influence methods, but they do not determine them. Stated otherwise, any method can be informed by one or more than one of contemporary paradigms or worldviews (Greene, 2007; Maxwell and Mittapalli, 2010). A table summarizing the five most common contemporary worldviews has been built for producing a "hand out" easy to read and retain for students (Table 1).

In mathematics, a combination is composed of one or more elements (each element being a combination of sub-elements, and so forth). Thus, a combination of worldviews is comprised of one or more worldviews, and a single worldview at the MM research team level can always be divided into variants. In other words, MM team members can apparently share the same worldview whereas they have different variants of this worldview. In previous work (Pluye et al., 2022), a literature review identified and described six combinations of worldviews at the MM research team level: three without integration of worldviews (a-paradigmatic, substantive theory, and single worldview) and three with integration (multiple worldviews, complementary strengths, and dialectical pluralism). These combinations are described below in terms of convergence and divergence of worldviews.

Table 1 The five most common contemporary worldviews in mixed methods research.

<i>Worldview</i>	<i>Ontology</i>	<i>Epistemology</i>	<i>Research purpose</i>	<i>Methodology</i>
Postpositivism	Evolutionary realism	Truthful scientific knowledge (but no truth)	Mainly to confirm hypotheses and generalize results of previous work, but sometimes to explore new ideas.	Mainly hypothetico-deductive, but potentially inductive. Biased data collection and analysis, e.g., influenced by researchers' values (influences at least partially controllable).
Social constructivism	Ontological relativism	Intersubjective knowledge	Mainly to explore new ideas (e.g., discover new scientific theories), but sometimes to confirm patterns and/or theories from previous work (e.g., transfer theories in other contexts).	Mainly inductive, but potentially deductive. Interpretation of data influenced by researchers' and participants' values.
Pragmatism	Action-related views of reality	Action-based knowledge	To explore and/or confirm action-oriented practical solutions and meaning-making.	Action-centered inductive and/or deductive data collection, analysis and solutions (what works).
Critical theory	Promotion of social justice via scientific understanding and explanations	Representation of the voice and views of the oppressed	To explore and/or confirm and reduce inequities. To enact individual empowerment and social changes for marginalized groups for instance.	Inductive and/or deductive participatory research methodologies and methods. Improvement of individual well-being and social justice. Research influenced by participants' values.
Critical realism	Ontological realism	Epistemological relativism	Mainly to confirm and/or test an a priori Middle-Range Theory (MRT), but sometimes to explore new ideas for building a new emerging MRT or improving an a priori MRT.	MRT-driven deduction, induction, abduction, and retroduction.

Three combinations without integration of worldviews

A-paradigmatic combination (convergence or divergence)

This combination suggests research methods, including MM, can be performed independently from worldviews. In this combination, paradigms (and personal worldviews) are “abstract conceptual ideas that can usefully inform” researchers’ methodologies broadly, i.e., they can help describe methods, but do not constrain them (Greene, 2007). Stated otherwise, the research purpose and specific research question(s) are more influential (compared to worldviews) for planning, conducting and reporting QUAL and QUAN methods, and their mixing. In this combination, there may be convergence or divergence of MM research team members’ worldviews because members set aside their worldviews. This means that there is no integration of worldviews pre-, per- and post-study. It does not mean that worldviews do not influence the MM study.

Substantive theory combination (convergence or divergence)

In this combination, MM can address research questions and mobilize concepts or theories that unify QUAL and QUAN methods, independent of the worldviews. For instance, a program theory can be used in a MM evaluation research, e.g., an ecological model or a logic model, independent of the research team members’ worldviews (Greene, 2007). The theoretical orientations are deemed more important than the philosophical underpinnings, e.g., a program theory becomes “the guiding framework for evaluation design and method choices, and the evaluation becomes theory-oriented” (Greene, 2007). In other words, the theory pertinent to a particular MM study is more influential (compared to worldviews) for planning, conducting and reporting QUAL and QUAN methods, and their mixing. Similar to the above combination, there may be convergence or divergence of MM research team members’ worldviews because members set aside their worldviews, which does not mean that worldviews do not influence the MM study.

Single worldview combination (convergence)

As shown in the above description of five common worldviews and in line with Greene (2007), several contemporary worldviews lend themselves to MM projects. There is convergence of MM research team members on one worldview for the project. This “single”

combination assumes all members share one similar worldview, or follow variants of the same worldview, and as such, reconciliation can be simple when there are worldview-related tensions between team members. Thus, there is no explicit integration of worldviews, but more than one variant can be at play.

Three combinations with integration of worldviews

Multiple worldviews combination (convergence)

In a MM study with this combination, multiple worldviews are present, but one is seen as particularly appropriate (Creswell et al., 2003; Teddlie and Tashakkori, 2010). Stated otherwise, although MM research team members are influenced by different worldviews that provide insight for the MM project, one worldview is seen as most influential and better aligned with the MM design, the methods for collecting and analyzing QUAL and QUAN data, and the way the results are reported. Researchers make their multiple worldviews explicit and provide a rationale for selecting one “best-fit” worldview for the entire MM project or sub-projects (Creswell and Plano Clark, 2011). Thus, MM research team members converge on one worldview for the project.

Complementary strengths combination (convergence)

In this combination, MM team members must assume that some worldviews are predominantly (but not necessarily) associated with QUAL methods, and must be kept separate from those predominantly (but not necessarily) associated with QUAN methods (Tashakkori and Teddlie, 2010; Greene, 2007). It follows, therefore, that methods for collecting and analyzing QUAL and QUAN data must be kept separate (e.g., a study may have a QUAN phase using one worldview followed by a QUAL phase using another worldview). Thus, QUAL and QUAN methods and results are reported separately, according to the corresponding worldviews, and their complementarity described. In a two-phase MM study, for instance, the integration of worldviews may take place where the QUAL and QUAN phases connect (a different worldview being used for each phase). In addition, pragmatism, critical theory and critical realism can help to integrate worldviews (Azzopardi and Nash, 2014; Christ, 2013; Shannon-Baker, 2016). Thus, MM research team members converge on the use of different worldviews depending on the component of the project.

Dialectical pluralism combination (divergence)

This combination assumes that the worldviews associated with QUAL and QUAN methods are different and interdependent (Johnson, 2008). Dialectical pluralism generates creative tensions leading to discovery and innovation. The similarities, differences and contradictions between the QUAL and QUAN methods and results must be described and discussed in the MM team meetings and publications. All worldviews have something to offer and the use of two or more different ones in a single MM study contributes to a greater understanding of the phenomenon under investigation (Greene and Caracelli, 2003). In a dialectical combination, “a reciprocal mutually respectful dialogic relationship between philosophical frameworks and methodological decisions” is warranted (Greene and Caracelli, 1997). MM team members can diverge on worldviews that influence the project, and must assume that (a) there are different ways to conceptualize reality, (b) knowledge is enhanced through respectful dialog among different conceptualizations, and (c) values of tolerance, acceptance, and equity are particularly important (Plano Clark and Ivankova, 2016). According to Shannon-Baker (2016), MM researchers must remain reflective throughout the dialectical inquiry; promote dialog among theories, data, and results; and integrate diverse viewpoints, particularly from tensions.

Proposed solution: recommendations for combining worldviews

This led to propose a conceptual framework, published elsewhere (Pluye et al., 2022), and recommendations to help students handle worldview-related tensions and combine worldviews in a MM project. The starting point is the description of worldviews at play and possible combinations. For example, MM research team members can read and discuss this chapter in a journal club, thereby eliciting and uncovering members’ worldviews. Similar to a compass, Table 1 can help the team to navigate the most common worldviews at play in their project.

Then, students and MM research team members can navigate the following four recommendations (R1, R2, R3 and R4), and select the most appropriate for planning and conducting their project (the most coherent with questions and objectives of the project). Research team members may decide to keep worldviews as indifferent kinds, avoid further debates, and adopt the a-paradigmatic combination, or the substantive theory combination. Or, should they share a worldview, they may elicit key characteristics of this worldview using the nominal group technique for instance (R1: move to single worldview). Indeed, R1 is the most straightforward recommendation. Then, it is also possible for team members to reach consensus on characteristics of a worldview that constitutes the “best fit” for their MM project (R2: move to multiple worldviews). Another option is that they discuss characteristics of their different worldviews, and use them for integrating QUAL and QUAN methods (R3: move to complementary strengths). Finally, they can define characteristics of their different worldviews, and select the dialectical approach (R4: move to dialectical pluralism).

This section adds to knowledge on worldviews in MM research at the research team level in terms of six possibilities how team members can mobilize and combine worldviews in their studies. Future educational research can empirically study how and why team members, e.g., a student and their mentors, combine worldviews in a MM study. This will provide useful practical examples and promote the explicit combination of worldviews (with convergence or divergence of worldviews) and the reporting of their consequences on planning, conducting and reporting MM research.

Convergence and divergence in mixed studies reviews

Convergence and divergence can be seen when conducting systematic mixed studies reviews, i.e., reviews combining qualitative, quantitative and mixed methods studies (Hong et al., 2017). This type of review is gaining in popularity due its potential to provide a more complete and deeper understanding of a complex phenomenon. The purpose of this section is to present examples of how convergence and divergence can be addressed when synthesizing evidence in mixed studies reviews.

Literature reviews of qualitative, quantitative and mixed methods studies

Literature reviews have been used by policy-makers, researchers and health service providers to inform decision-making (Bunn et al., 2015). Traditionally, reviews have given preference to QUAN evidence, e.g., systematic reviews of randomized controlled trials (RCTs) with meta-analysis to assess the effectiveness of educational interventions or programs. However, a focus on QUAN evidence is insufficient in areas where research is not dominated by RCTs (Goldsmith et al., 2007), as seen in educational research (Gough and Thomas, 2016). In addition, RCTs are not appropriate nor sufficient to address complex and multifaceted questions such as “Why does it work?”, “How does it work?”, and “What works for whom in what context?”. Such questions can be addressed in mixed studies reviews with the synthesis of QUAL and QUAN evidence (Dixon-Woods et al., 2004; Pluye and Hong, 2014; Pluye et al., 2016).

In education, Randolph (2009), among others, proposes guidance for students to plan, conduct and report qualitative and quantitative reviews with synthesis of QUAL and QUAN evidence, respectively. In contrast, there is a growing interest in synthesizing QUAL and QUAN evidence derived from qualitative, quantitative and mixed methods studies using a diversity of approaches and designs. This new type of review has been labeled with various terms such as integrative review (Whittemore and Knafl, 2005), mixed methods review (Harden and Thomas, 2005), mixed methods research synthesis (Heyvaert et al., 2016), mixed research synthesis (Sandelowski et al., 2006), and mixed studies review (Pluye et al., 2009a). These reviews can be used to provide (a) a deeper understanding of quantitative evidence, (b) a statistical generalization of findings from qualitative evidence, and (c) a corroboration or complementarity of knowledge obtained from quantitative and qualitative evidence (Pluye and Hong, 2014).

Synthesis designs in mixed studies reviews

A challenge when performing mixed studies reviews is the combination of findings from a diversity of studies (qualitative, quantitative and mixed methods). To address this challenge, a review of 459 systematic mixed studies reviews has been conducted and identified two main synthesis designs (Hong et al., 2017): convergent and sequential (described below). Based on where the integration occurred, three subtypes of convergent synthesis design were identified: data-based, results-based and parallel-results. The synthesis designs can provide guidance on how to integrate evidence, and report the added value and insight gained of this integration.

First, in the *data-based convergent synthesis design*, all included studies are analyzed using a same synthesis method and results are presented together. Since only one synthesis method is used for all evidence, data transformation is involved (e.g., qualitative data are transformed into numerical variables/values, or quantitative data are transformed into categories/themes). This transformation may reveal convergence or divergence between QUAL and QUAN data. This design usually addresses one review question. Among the systematic mixed studies reviews using this design, three main objectives are found. The first objective is to describe the findings of the included studies; the synthesis methods range from summarizing each study to grouping main findings. The second objective is to identify and define main concepts or themes using a synthesis method such as qualitative thematic synthesis (e.g., identify main barriers and facilitators to the implementation of a program, or types of impact). The third objective is to establish relationships between the concepts and themes identified from the included studies, or to build a conceptual framework (or theoretical model).

Second, in the *results-based convergent synthesis design*, the qualitative and quantitative evidence are analyzed and presented separately, but integrated using another synthesis method. The integration can consist of comparing or juxtaposing the findings of qualitative and quantitative evidence using tables and matrices, or reanalyzing evidence in light of the results of both syntheses. This comparison may reveal convergence or divergence between QUAL and QUAN results. For example, a review was interested in determining the interventions to optimize Type I diabetes care and management in school setting (Edwards et al., 2014). They performed (a) a synthesis of the QUAN studies on the intervention effectiveness, (b) a synthesis of studies of people’s viewpoints, and (c) an overarching synthesis matrix integrating the results of both syntheses. This comparison consisted of mapping the best practices against barriers and facilitators to see the extent to which the interventions were effective and addressed the barriers identified by young people and school personnel.

Third, in a parallel-results convergent design, QUAL and QUAN evidence are analyzed and presented separately. The integration occurs during the interpretation of results in the discussion section. This can reveal convergence and divergence between QUAL findings and QUAN results. For example, in a review on computerized virtual patients in health professional education, the authors studied two review questions: Q1. What is the learning effectiveness of virtual patients? and Q2. What virtual patients design features are associated with higher learning effectiveness? (Cook et al., 2010). The evidence for each question was reviewed separately (using meta-analysis for Q1 and thematic synthesis for Q2) and brought together in the discussion and recommendations.

Fourth, in a sequential design, there is complementarity between QUAL and QUAN evidence from included studies, i.e., a form of convergence. This design involves a two-phase approach where the data collection and analysis of one type of evidence occur after, and are informed by the collection and analysis of the other type. This design usually addresses one overall review question with sub-questions and both syntheses complemented each other. For example, in a review aiming to identify the impact of clinical information-retrieved technology on physicians, residents and medical students, a thematic qualitative synthesis of the QUAL studies (synthesis 1) led to identify types of impact of searches for information (Pluye et al., 2005). Then for each type of impact, a descriptive statistical synthesis of the QUAN studies was performed to identify the frequency of searches (synthesis 2 informed by results of synthesis 1).

Convergence and divergence in synthesis of QUAL and QUAN evidence

The science of systematic review grew from the need of making sense of convergences, divergences and inconsistencies between studies. For example, Sen. Walter Mondale, a former vice-president of the United States, provided the following statement during the American Education Research Association conference in 1971: "For every study, statistical or theoretical, that contains a proposed solution or recommendation there is always another, equally well documented, challenging the assumptions or conclusions of the first. No one seems to agree with anyone else's approach. But more distressing: no one seems to know what works. As a result I must confess, I stand with my colleagues confused and often disheartened." (cited in Light and Smith, 1971).

Since the 1970s, systematic reviews have been developed through formal and rigorous methods to better study the convergences and divergences between included studies (Hong and Pluye, 2018). For example, meta-analysis was one of the first methods developed by Gene Glass, a statistician in educational psychology, to statistically combine the results of several studies (Glass, 1976). Part of the evidence-based practice movement, it is recommended to conduct and use high quality systematic reviews and evidence synthesis methods to support educational practice (Davies, 2000).

Considering that the focus of this section is on the synthesis process in systematic mixed studies reviews, the literature on process studies especially in the fields of management provides insight into these concepts. In line with Langley et al. (1995), the convergent synthesis can be defined as a process of gradual and successive comparison and interpretation of QUAL and QUAN evidence derived from included qualitative, quantitative and mixed methods studies. Researchers are working forward in a non-linear manner guided by a cognitive representation of new data-based synthesis, or results-based synthesis, or interpretation of results to be created. Thus, they identify complementarities, corroborations, similarities, differences and contradictions, describe how the QUAN and QUAL evidence are integrated, and discuss the insight gained from this process. Furthermore, in line with Van de Ven (1992), a sequential synthesis design can be defined, according to a developmental perspective (phase-1 informing phase-2; and phase-2 building on the results of phase-1), as a change of focus at the level of data or synthesis over time, and as a cognitive transition into a new phase (e.g., from qualitative to quantitative, or from quantitative to qualitative evidence) where QUAL and QUAN evidence complement each other.

As mentioned, integration of QUAL and QUAN methods is an inherent component of MM research, specifically the integration of QUAL and QUAN evidence. In systematic mixed studies review-related syntheses, this integration requires to explore the relationships between results of included studies (convergences) and provide explanations of heterogeneity (divergences) (Thompson Coon et al., 2019). Based on different perspectives and different sources of evidence, convergences can reinforce the implications and recommendations issued from a review (Andrews, 2005). Yet, there can be divergences in priorities, values, language, meaning, agenda and time scale between researchers, practitioners and policy makers (Harlen and Deakin Crick, 2004). To address these divergences, there is a need for closer working collaboration between these parties (Harlen and Deakin Crick, 2004). For example, a mixed studies review on decisional needs assessment of patients with complex care needs used a participatory research approach in which multiple users were involved at the different steps the review process (Bujold et al., 2017).

Another source of divergences can be found in the heterogenous nature of included studies in mixed studies reviews. Indeed, the studies usually address different questions and perspectives, adopt different paradigms, and use different methodologies. Heterogeneity can also be found in terms of populations, interventions, outcomes and studies' quality. However, divergences are rarely reported; e.g., four of a sample of 59 mixed studies reviews (7%) mentioned some form of divergence, i.e., discrepancies between QUAL and QUAN evidence (Pluye et al., 2009a). This does not necessarily mean that divergences are ignored, but that they are not considered essential or worth of reporting. In contrast, this chapter argues that obtaining divergent results should not be viewed negatively because they provide a more comprehensive and nuanced understanding of the phenomenon under study (Thompson Coon et al., 2019).

The integration of QUAL and QUAN evidence requires to use an iterative process, and often go back to the data to better explore how they match and mismatch. For example, in a review on nonpharmacological school-based interventions for attention deficit hyperactivity disorder, an interweave synthesis approach was used to identify patterns and links between and across syntheses (Thompson Coon et al., 2019). This approach required to start once the reviewers developed an understanding of the initial findings, be immersed in the data, and use intersubjective questions. This review also involved discussion of the findings of the overarching synthesis with stakeholders.

Specifically in syntheses, a strategy to address convergences and divergences is to perform a sensitivity analysis, which consists of repeating the synthesis by excluding a set of particular studies to explore how the results obtained in the synthesis are modified (Deeks et al., 2019). For example, in a mixed studies review on factors influencing the implementation of mental health recovery into services, sensitivity analysis was conducted to determine whether the quality of the included studies influenced the findings of the synthesis (Piat et al., 2021). In doing so, reviewers verified whether some themes identified were solely based on lower-quality studies.

Convergences and divergences can also be explored using subgroup analysis that involves splitting the data into subsets of studies (such as particular geographical locations, types of interventions, types of populations, etc.) (Deeks et al., 2019). For example, in a review on healthy eating among children aged 4–19 years, the findings from the qualitative synthesis on the views of children were compared with results from controlled trials on the effectiveness of interventions to promote children's fruit and vegetable consumption (Thomas et al., 2004). This allowed to identify interventions that match the recommendations derived from the views and experiences of children on the consumption of fruits and vegetables. Subgroup analysis was then conducted to study whether interventions that match recommendations show bigger effect sizes.

Convergence and divergence in primary MM research

In primary MM research, convergence and divergence of QUAL and QUAN evidence (data or results) can occur no matter the type of MM design, and can derive from any type of integration. Nowadays, convergence and divergence in MM empirical research are well-known. In the MM literature, convergence is almost everywhere, whereas divergence is seldom mentioned. For example, 21 MM textbooks were reviewed in preparation for this chapter: nine presented only convergence of QUAL and QUAN evidence, and 12 allotted some space to divergence. In addition, a snowball technique was performed, e.g., using the Scopus database, and multiple reference articles were also reviewed. The analysis of these articles suggests that few MM empirical studies report divergence between QUAL and QUAN evidence, and little truly focus on divergence. Based on this sample of MM textbooks and reference articles, the definitions of convergence and divergence between QUAL and QUAN evidence in primary MM research are summarized in the following sections and Table 2, and illustrated using MM education-related empirical studies.

Convergence

In the MM literature, the concept “Convergence between QUAL and QUAN evidence” refers to two main sub-concepts: corroboration and complementarity. First, corroboration confirms or validates scientific data or results using parallel QUAL and QUAN evidence. This correspondence of evidence enhances their trustworthiness (evidence from QUAL methods supported by evidence from QUAN methods, and vice versa). Stated otherwise, the corroboration of QUAL and QUAN evidence from different sources, methods and investigators strongly reinforces a proposition about a phenomenon when there is theoretical and conceptual coherence, whatever the MM team researchers' worldviews and the methodologies at play. In corroborating evidence, the focus is on the verification of the quality of QUAL and QUAN methods, which is needed to confirm that the same conclusion from QUAL and QUAN evidence is trustworthy when the verification concludes that QUAL findings are credible, dependable and confirmable, while the QUAN results have internal validity, and are reliable and comparable. Specifically in MM case studies, corroboration refers to “confirming cases,” i.e., cases supporting a pattern of cases (e.g., a subset of cases presenting similarities in terms of QUAL and QUAN data). Furthermore, MM researchers and students should be cautious about a limitation of corroboration, that is the risk of spurious corroboration when QUAL and QUAN evidence share the same source of error, e.g., with respect to the sampling. In the literature, synonyms of corroboration are consensus, consistency, consonance, and similarity. Corroboration is sometimes associated with the trigonometric metaphor “Triangulation,” which has been highly controversial for the past three decades, and should be abandoned due to its vagueness and polysemy in scientific publications (Morgan, 2019).

In the following example, QUAL and QUAN evidence were obtained through separate data collection and analysis. Rosenkranz et al. (2015) sought to study what motivates medical students to do research. This MM study integrated a cross-sectional quantitative survey and a qualitative descriptive research, which were conducted in a concomitant parallel manner. The QUAN component consisted of 806 eligible students among which 579 (71.8%) completed the survey structured questionnaire. Survey results revealed that students who experienced a sense of achievement through research activities were more likely to perceive future research activities in a positive manner. In the QUAL component, all medical students were invited to interviews on prior research experiences and perceived barriers/facilitators to do research. The qualitative data analysis was informed by the Self-Determination Theory (three domains: autonomy, competence and relatedness). Then, QUAN results and QUAL findings were compared according to the theoretical dimensions and factors, both in a narrative and a tabulated format: “content or thematic areas were identified from both datasets, compared and contrasted; integration occurred at the point of final data interpretation, by identifying groupings

Table 2 Definitions of convergence and divergence between QUAL and QUAN evidence.

<i>Authors: research domain(s)</i>	<i>Convergence of QUAL and QUAN evidence</i>	<i>Divergence of QUAL and QUAN evidence</i>
Bazeley (2012), Bazeley (2018): multidisciplinary ^a	Complementarity of QUAL and QUAN evidence (better understanding, and generating stronger inferences, i.e., better supported by evidence, or more generalizable, or both). e.g., map complementary analysis (explore, sort by categories, compare or merge, describe and elaborate). Corroboration (confirming or validating using parallel evidence).	Dissonance of QUAL and QUAN evidence (different meanings). Varying intensity from inconsistencies, differences, disagreements, contradictions, conflicts, discords, or paradoxes. Three strategies for handling divergence: verify methods, reconcile divergences in a plausible way (context exploration, theory renewal, interpretive explanation), or initiate new research phase or project.
Caracelli and Greene (1993): evaluation studies	Corroboration and correspondence of evidence. Complementarity (overlapping distinct aspects of the phenomenon; enhancing, illustrating, or clarifying QUAN evidence with QUAL evidence, or vice versa).	Contradictions and paradoxes. One strategy for handling divergence: initiate new research phase or project (divergence recasting research questions).
Creamer (2018): multidisciplinary	Complementarity (gains of using QUAL and QUAN methods). Corroboration of evidence (enhancing validity).	
Creswell and Plano Clark (2018): multidisciplinary	Congruent evidence (comparison in a narrative or table format).	Discrepant or incongruent evidence (comparison in a narrative or table format). Conflicts, contradictions, discrepancies, and inconsistencies of evidence. Three strategies for handling divergence: verify validity of evidence (absence of methodological problems), reconcile divergences in a plausible way (reanalysis of datasets), or initiate new research phase or project.
Curry and Nunez-Smith (2015): health sciences	Coherent evidence. Complementary evidence. Spurious convergence (QUAL and QUAN evidence sharing same bias or source of error).	Conflicting, dissimilar, divergent, or inconsistent evidence (highlighting novel findings, discovery, insights and unanswered questions). Three strategies for handling divergence (citing Pluye et al., 2009b).
Erzberger and Kelle (2003): multidisciplinary	Corroboration of evidence: triangulation trigonometric metaphor (focus on verification or validation of methods). Complementary evidence: QUAL and QUAN evidence supplementing each other (adding breadth and depth to analysis, providing a more complete picture compared to QUAL or QUAN evidence alone). Potential spurious convergence (methods biased in the same way).	Inconsistent or contradictory evidence (pointing to new insights). Three strategies for handling divergence: verify validity of evidence (absence of methodological problems), reconcile divergences in a plausible way (reanalysis of datasets), or initiate new research phase or project.
Fetters and Molina-Azorin (2017): multidisciplinary	Corroboration (confirming same conclusion from QUAL and QUAN evidence). Complementarity (QUAL and QUAN methods providing non-conflicting evidence on different aspects of a phenomenon). Variant of complementary evidence: expansion (QUAL and QUAN evidence providing a broader overlapping understanding compared to QUAL or QUAN alone).	Discordance or conflicts. Three strategies for handling divergence (citing Pluye et al., 2009b).
Fetters (2020): multidisciplinary	Complementary evidence (evidence from QUAL methods enhanced by evidence from QUAN methods, or vice versa). Corroborating evidence (evidence from QUAL methods supported by evidence from QUAN methods, or vice versa).	Corroboration disconfirmed. Contradiction, discordance, conflict or paradox (based on the comparison and interpretation of evidence). Three strategies for handling divergence (citing Pluye et al., 2009b).

Table 2 Definitions of convergence and divergence between QUAL and QUAN evidence.—cont'd

<i>Authors: research domain(s)</i>	<i>Convergence of QUAL and QUAN evidence</i>	<i>Divergence of QUAL and QUAN evidence</i>
Greene (2007) and Greene (2015): social sciences	Complementarity (developing broader, deeper, and more comprehensive social understandings of complex social phenomena by using methods that tap into different facets or dimensions of these phenomena). Corroboration, consistency, consonance, or consensus (based on the comparison of QUAL and QUAN evidence).	Clashes, conflicts, divergence, dissonance, paradox, or puzzle (comparison of evidence generating new unanticipated perspectives, understandings and insights). One strategy for handling divergence: initiate new research phase or project (generative pathway).
Ivankova and Kawamura (2010): multidisciplinary Mathison (1988): education	Synergy (better understanding and gaining insights). Corroboration (QUAL and QUAN evidence from different sources, methods and investigators supporting a single proposition about a phenomenon).	Contradictory evidence (revealing the value of combining methods). Inconsistent evidence (disconfirming a single proposition, and presenting alternative propositions containing inconsistencies and ambiguities). Contradictory evidence (opposing views of the social phenomenon being studied). One strategy for handling divergence: reconcile divergences in a plausible way.
Moffatt et al. (2006): health sciences	Similarities. Complementarity (exploring QUAL and QUAN evidence separately: each addressing distinct, though related, aspects of a phenomenon).	Discrepancies. Discord. Of 6 strategies for handling divergence, 1 actually refers to convergence (complementarity), and 5 can be merged in the following 3 main categories: (a) VERIFY validity of evidence (absence of methodological problems); (b) RECONCILE divergences in a plausible way (reanalysis of datasets including the comparison of the participants from each component, and the exploration of whether the intervention under study worked as planned and whether the constructs and concepts under study in each component match, e.g., health outcomes); and (c) INITIATE new research phase or project (collecting further data to allow more comparisons).
Morgan (2014) and Morgan (2019): social sciences	Corroboration: convergent evidence (increasing credibility of similar evidence from different methods: "QUAL = QUAN"). Complementarity (covering different aspects of a phenomenon: "QUAL + QUAN").	Divergent evidence (raising doubts about whether the different methods studied a similar phenomenon). One strategy for handling divergence: initiate new research phase or project (generative pathway).
Nightingale (2009) and Nightingale (2016): environment	Complementarity (different methods with evidence complementing each other when paradigmatic and theoretical coherence). Corroboration (ensuring the robustness of methods when conceptual coherence—similar constructs).	Divergence and gaps (QUAL and QUAN evidence failing to make sense in relation to each other). Two strategies for handling divergence: verify validity of evidence (e.g., the absence of theoretical error), or reconcile divergence in a plausible way (each data set revealing a different understanding, e.g., referring to different paradigms).
Plano Clark and Ivankova (2016): multidisciplinary	Complementary evidence (synergistic responses to a question with additional coverage and enhanced effectiveness). Confirming evidence (verifying theories). Convergent evidence (answering similar questions with greater certainty and stronger inferences).	Divergent evidence (uncovering divergent results).

Table 2 Definitions of convergence and divergence between QUAL and QUAN evidence.—cont'd

Pluye et al. (2009b): multidisciplinary		Three strategies for handling divergence: verify the quality of methods, reconcile divergences in a plausible way, or initiate new research phase or project.
Sammons (2010): education	Synergistic understanding of educational effectiveness (connection or comparison of evidence, each method informing the other in a reciprocal or dialectical manner).	
Teddlie and Tashakkori (2009) and Teddlie and Tashakkori (2010): social and behavioral sciences	Convergence of QUAL and QUAN evidence. Confirming cases (verifying patterns).	Dissimilarity or divergence of QUAL and QUAN evidence (providing insights into complex aspects of a phenomenon). Disconfirming cases (refuting patterns).

^aBazeley (2018) includes a chapter on inherently mixed integration strategies such as MM case study, social network analysis and qualitative comparative analysis (QCA), which are centered on convergence and divergence, e.g., within cases and across cases (intensive case review necessary when divergent cases).

of content areas, presenting both datasets in tables and generating narrative descriptions for each conceptual grouping" (p. 4). The comparison highlighted the corroboration of the QUAN results and QUAL findings, e.g., about intrinsic motivators associated with confidence in (competence) and clinical relevance of (relatedness) research activities. Integrated results led to propose a conceptual framework explaining the students' motivation to do research, and recommendations to redesign the curriculum for improving their motivation.

Second, complementarity between QUAL and QUAN evidence can generate more knowledge on the phenomenon under study compared to QUAL or QUAN evidence alone. It addresses distinct, though related, aspects of a phenomenon. For example, it can develop a broader and deeper understandings of complex phenomena by using methods that tap into different dimensions and facets of these phenomena, including through QUAL- and QUAN-informed theoretical models (Kawamura et al., 2009). It can also enhance, illustrate, and clarify QUAN evidence with QUAL evidence, and vice versa. Typically, complementarity leads to a more comprehensive understanding, or more generalizable inferences, or both. In other words, the complementarity of QUAL and QUAN evidence from different sources, methods and investigators adds breadth and depth to data analysis, and provides more complete results because QUAL and QUAN evidence supplement each other when there is theoretical and conceptual coherence, regardless of the MM team researchers' worldviews and the methodologies at play. In complementing evidence, the focus is on the synergy between methods as each method informs the other, and can gain more insights in a reciprocal manner, e.g., evidence from QUAL methods is enhanced by evidence from QUAN methods, and vice versa (synergistic responses to the research questions). In the literature, synonyms of complementarity are coherence, congruence and synergy. A variant of complementarity seems to be "expansion," which refers to QUAL and QUAN evidence providing a broader overlapping understanding compared to QUAL or QUAN evidence alone (Greene, 2007). This notion implies that QUAL and QUAN evidence can address both similar and distinct (interrelated) aspects of a phenomenon.

In the following example, QUAN and QUAL evidence were obtained in an interdependent manner. Bindiganavile Sridhar et al. (2013) studied the validity of the Information Assessment Method (IAM), which supports popular Continuing Medical Education (CME) programs. The IAM allows physicians to report the relevance, cognitive impact, intention to use and expected patient health benefits of CME information. Physicians read information, rated it using IAM, and earned CME credit for this individual reflective learning activity. The IAM items were based on literature reviews and qualitative research studies. Researchers aimed to assess the content validity of IAM items from the users' perspective using a MM validation study. Content validity is composed of relevance (are items appropriate to assess the construct?) and representativeness (do items represent all aspects of the construct?). QUAN and QUAL methods were used to evaluate the relevance and representativeness of IAM items, respectively. The QUAN component consisted in a longitudinal quantitative study, 40 family physicians completed 1767 IAM questionnaires (hereafter IAM ratings) over 320 days, which allowed the researchers to calculate a relevance ratio for each item, namely the number of items rated divided by the total number of ratings. The QUAL component was a qualitative multiple case study in which these physicians were interviewed to explain their ratings. A case was a CME information content rated by a physician using the IAM. "The integration of the quantitative and qualitative methods occurred at the stage of interpreting quantitative (relevance) and qualitative (representativeness) results" (p. 5). For each IAM item, QUAN and QUAL results were compared and interpreted (e.g., item relevant and representative) in a tabulated format (side-by-side comparison of the relevance ratio and the participants' perceived representativeness). Then, a decision was made, e.g., item not changed, modified or removed, by a multidisciplinary expert panel using a set of guiding principles. Overall, the content validity of 16 IAM items was supported, and these items were not changed. Nine other items were modified, and three new items were added. This led to a content validated version of the IAM questionnaire for CME programs.

Divergence

In the MM literature, the concept “Divergence between QUAL and QUAN evidence” refers to a continuum from inconsistencies to paradoxes, and three strategies for handling divergence (verification, reconciliation and initiation). These concepts and strategies will be described and illustrated using MM education-related empirical studies in the next sections. Specifically, Scopus identified 52 open access articles published in 2020 with “mixed method*” in the title and “education” in the title/abstract/keyword. Of those, 22 were excluded because they did not refer to complete empirical studies (e.g., protocols). Of the 30 remaining articles, three (10%) reported differences between QUAL and QUAN results and are presented below (Allison et al., 2020; Dashtestani, 2020; Mankelow et al., 2020).

Definition and examples

Divergence means that QUAL and QUAN evidence fail to make sense in relation to each other. Regarding the meanings of QUAL and QUAN evidence, divergence varies in intensity from inconsistencies (nuanced meanings) to ambiguities, discrepancies, discordances, dissimilarities, dissonances, incongruencies, differences, disagreements, contradictions, conflicts, discords, oppositions, clashes and paradoxes (antagonistic meanings). Divergence is usually reported after a comparison and interpretation of QUAL and QUAN evidence in a narrative, or table format, or both (or in a theoretical format (Kawamura et al., 2009)). It can also be sought by design, e.g., in building cases. It can highlight methodological issues, novel findings (pointing to new insights) and unanswered questions. When corroboration is the focus, divergence initially raises doubts about whether the QUAL and QUAN methods study a similar phenomenon. Then, it can be challenging (leading to modify the proposition about the phenomenon under study) or disconfirming (leading to a counter-proposition) when methodological and theoretical issues are discarded. For example, divergence can disconfirm cases and refute anticipated patterns. When complementarity is the focus, divergence can be initially puzzling, then generates a new unanticipated understanding of the different aspects of the phenomenon under study (showing the value of combining methods by providing insights into complex aspects of a phenomenon). Two examples are presented below.

First, Allison et al. (2020) assessed an educational health website on infections and antibiotics for school teachers and students. They combined a survey and an interpretive qualitative study (scenario-based observation of teachers). The QUAN results showed that almost all teachers liked the website (97.1% would use it themselves, and 98.1% would recommend it to others). In contrast, QUAL findings revealed some drawbacks such as difficulties to access the student’s section of the website and the resources for training teachers.

Second, Dashtestani (2020) assessed the teachers’ acceptance, learning achievements and satisfaction regarding online courses in higher education. They compared the perceptions of teachers and university faculty members using surveys and a qualitative descriptive study (semi-structured interviews). Overall, QUAL findings corroborated QUAN results. However, QUAN results showed that teachers were positive about online courses regarding all outcomes, whereas QUAL results revealed that online courses were seen (a) less rigorous compared to face-to-face courses, (b) limited by technical and Internet connection problems, and (c) lacking human interaction and practical content. In addition, teachers reported that some of them did not take online courses seriously, while certificates of online courses lacked credibility, e.g., low employers’ acceptance. Furthermore, students had low knowledge of the content from online courses, and the services they received did not match the tuition fees.

Three strategies for handling divergence

Table 2 shows that three main strategies for handling divergence of QUAL and QUAN evidence are proposed for MM students and researchers: verification, reconciliation and initiation. These strategies require (a) a critical appraisal of the methodological quality of the QUAL and QUAN methods, (b) the reanalysis and interpretation of the available QUAL and QUAN evidence, and (c) the collection and analysis of additional evidence when needed (Moffatt et al., 2006; Pluye et al., 2009b). The selection of the appropriate strategy is summarized in Fig. 1. Definitions and empirical illustrations of these strategies among educational research are described in the following sub-sections.

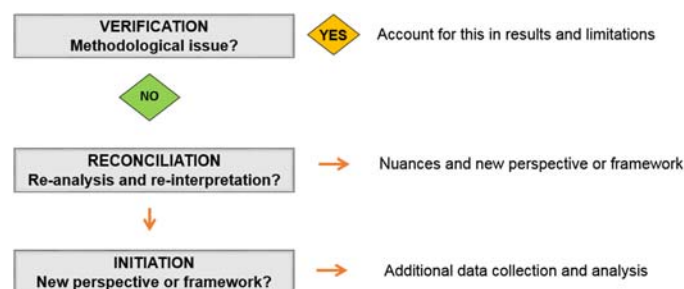

Fig. 1 Three strategies for handling divergence between QUAL and QUAN evidence.

Verification

Verification must be the first step to follow when there is divergence. For example, this strategy can lead to suggest that QUAL or QUAN evidence or both lacks trustworthiness, or that the results of the MM study are incomplete or inadequate, which might be the consequences of theoretical and conceptual incoherencies. In these situations, limitations must be reported in a transparent manner. Initial evidence must not be excluded, but reinterpreted (e.g., some QUAL or QUAN results can be reinterpreted as inconclusive due to methodological limitations). Rare empirical illustrations of verification were found among the MM empirical studies. It does not mean that it was absent or ignored, but that other information was worth reporting in the allotted word limit of publications for instance.

By way of illustration, [Parr et al. \(2021\)](#) studied teachers' motivations and ability to teach and their emotions when teaching. QUAL findings did not suggest a relation between perceived teaching abilities and teaching emotions. Yet, QUAN results suggested perceived teaching abilities were associated with greater teacher enjoyment and less anger. This led authors to verify potential methodological issues. Specifically, authors assessed the QUAN validity and QUAL credibility of their results, and the quality of their mixed methods "meta-inferences" (i.e., the integration of QUAL and QUAN results). They did this by "coming to consensus on the coding of all qualitative themes, ensuring that all quantitative measures had acceptable internal consistency reliability, and employing multiple mixed legitimization techniques" (p. 5). In turn, this led authors to find that this divergence might be associated with conceptual inconsistencies: QUAL interviews were broadly informed by a theory, whereas QUAN survey items represented each theory concept, dimension and facet (see quote below).

We did not prompt for specific motivations defined by FIT-Choice theory in qualitative interviews, but quantitative surveys had items for each FIT-Choice motivation. We took a broad approach in our interview protocol to allow for motivations not yet defined in the literature to emerge. However, an unintended consequence was that teacher interviewees talked relatively little about their perceived teaching abilities. It is plausible that the methodological constraints led to these discrepant findings (p. 11).

In another example, some divergences between QUAL and QUAN data were interpreted as inconclusive ([Pluye et al., 2013](#)). The contradictions led to reinterpret some data that initially suggested benefits of the intervention. This MM study was aimed to investigate family physicians' behavior with respect to searching for information in a specialized web database. The study integrated a longitudinal QUAN component and a QUAL multiple case study. Specifically, cases were critical searches for information by practicing physicians for specific patients. Critical searches had clear consequences in terms of patient health outcomes. The QUAN data collection documented physicians' searches for clinical information as well as their reflection on each search (physicians' ratings of the relevance, the cognitive impact, and the use of information). For each search, physicians completed the above-mentioned IAM questionnaire and earned CME credits. Guided by QUAN data, 39 physicians were interviewed about 365 rated searches. Interviews collected the physicians' explanation of the clinical situation, the objectives of the search, their use of this information, and the benefits for their patients. QUAL data included log reports, archives, and interview transcripts. Of 365 searches, 143 (39.2%) were forgotten or not used for a specific patient at the time of the interview. With respect to other searches, QUAN and QUAL data were merged into clinical stories (hereinafter called vignettes).

For each vignette, divergences between QUAL and QUAN data were identified as follows. Transcripts were analyzed by three researchers. The first researcher assigned extracts of transcripts to themes by going back and forth from textual data to themes, and synthesized QUAN and QUAL data into an initial vignette (highlighting potential divergences). The second researcher reviewed all data corresponding to the initial vignettes. Disagreements between these researchers regarding the interpretation of the data (summarized in the vignettes) were resolved by discussion and consensus. To ensure rigor in mixing data, they specifically discussed the divergences, and systematically documented strategies to solve these issues, e.g., they removed 34 (9.3%) unclear searches from the set of critical searches. In other words, they verified the trustworthiness of QUAL data, and classified these unclear searches as non-critical, i.e., searches without clear patient health outcomes. Then, the third researcher, a practicing physician, independently reviewed transcripts and vignettes corresponding to 188 (51.5%) critical searches with patient health benefits. He judged the trustworthiness of the clinical content, and the relationship between the use of information and patient health benefits. For each vignette, he answered the following two questions: Is this clinical story clear, convincing and coherent, from a medical perspective? Can these reported patient health outcomes be associated with these information hits and information use? No stories were deemed to be untrustworthy.

Reconciliation

Reconciliation is the second step to follow when there is divergence without methodological issues. This strategy must be performed in a transparent manner, and may occur when the divergence between QUAL and QUAN evidence can be reinterpreted in a sense-making plausible manner, e.g., following the reanalysis of available data in accordance with divergence-related insights. Such reanalysis can include an evaluation of the context and of the theoretical and conceptual coherence of methods. For example, reanalysis can consist of comparing participants from each method, determine whether the intervention under study worked as planned and whether outcomes match ([Moffatt et al., 2006](#)). Reconciliation can suggest nuances, e.g., through the integration of QUAL- and QUAN-informed theoretical models ([Kawamura et al., 2009](#)), and a new perspective or framework. However, QUAN editors

and peer-reviewers might call the “reanalysis” a “post-hoc analysis,” which is usually reported in the discussion section of scientific publications (not in results). In the following education-related example, the divergence between QUAL and QUAN data and results was reconciled.

Using a MM research study, [Huwendiek et al. \(2017\)](#) assessed 5th-year medical students’ acceptance, educational impact, and psychometric characteristics of two types of test used in pediatric exams: Context-Rich Single Best Answer questions (crSBA: patient vignette followed by one question with one correct answer) and Key-Feature Problems (KFP: patient vignette followed by more than one questions requiring free-text entry responses). QUAN data were exam results of 377 students and QUAL data were collected in eight focus groups. While QUAN results showed no difference in difficulty between the two types of test, QUAL findings revealed that KFP were perceived more difficult than crSBA questions. Based on the literature (see quote below), this divergence was reconciled as follows: “It may be hypothesized that if students truly believe that crSBA are easier, in the sense that these require less critical thinking, an examination that is purely crSBA-based could be perceived as less challenging” (p. 482). Interestingly, students who were given KFP performed better to the final practical test of clinical competences.

Our data indicate that KFPs with a long-menu response format provide a greater stimulus for the intense study of clinical reasoning than do crSBAs. This educational effect of KFPs has not been previously reported for clerkship students. A few studies, however, have demonstrated that the question format, notably the response format, can affect student learning. [One study] for instance, recently pointed out that the response format can indeed have an impact on the incidence of cueing, which again can impact perceived difficulty. In their study, they made a comparison between multiple choice-type and open-ended questions, presenting a first group of students with open-ended questions, followed by multiple choice questions, and a second group with the same questions in the reverse order. Irrespective of the format seen first, multiple choice scores resulted higher than those of the open-ended questions. The observed pattern suggests that it was cueing rather than memory for prior questions that led to increased multiple choice questions scores (p. 482).

Another example of reconciliation can be seen in the above-mentioned CME study ([Pluye et al., 2013](#)). Some divergences between QUAL and QUAN data were considered minor differences and easily reconciled, e.g., in the vignette on “Testing for multiple myeloma.” This vignette shows that on June 20, 2008, MD08 did a search at work, by themselves, and during an encounter with a patient (QUAN data—IAM responses). They retrieved one information hit about multiple myeloma and plasma cell malignancies. The reported search objectives were to address a clinical question and to look up something they forgot (QUAN data—IAM responses). “I was primarily just double-checking to see what sorts of tests I should be doing to either rule in or rule out the multiple myeloma as the diagnosis in this patient. [...] It was to make sure that there wasn’t something that I had forgotten in terms of specifically what to check in the urine” (QUAL data—interview). MD08 found relevant information in the specialized database that was provided by the research team, and used it for a specific patient (QUAN data—IAM response). They used this information to maintain and justify the diagnosis of the patient: “It was in terms of ordering the appropriate diagnostic test. [...] I would say that it [the information] probably justified it [the management] more than modified” (QUAL data—interview). No information-related patient health outcome was reported. There was a divergence between the cognitive impact of information reported in the IAM responses (rating “I recalled something”) vs. the interview: “*It was a question of confirming this thing about the urine part of the assessment, specifically.*” Whereas the former refers to a memory issue, the latter suggests that MD08 looked for information to confirm that they were doing the right thing. Researchers revised the interview and the archive (the informational content retrieved by MD08), and concluded that there may be something in the information content that confirmed MD08 was doing the right thing (urine test) while some details were recalled (a specific test). This reconciliation led researchers to include two types of cognitive impact in the final vignette (recall and confirmation).

Initiation

Initiation constitutes the third step to follow when there is divergence. This strategy begins with a new perspective or framework that emerges from QUAL and QUAN evidence. It consists of a generative process leading to collect additional data. Initiation requires two sub-steps: asking new research questions (or recasting questions), and collecting and analyzing new data to further examine from a new perspective or framework. By way of illustration, [Moffatt et al. \(2006\)](#) evaluated impacts of welfare rights advice on health and social outcomes among an aged population. While QUAL findings suggested many different impacts, QUAN results indicated no impact. Thus, methods were critically appraised, data reanalyzed, and additional data collected and analyzed.

[Rossman and Wilson \(1985\)](#) also used initiation. They aimed to evaluate the perceived usefulness of Regional Educational Service Agencies (RESAs) from the perspective of school administrators and teachers. They combined a survey with a qualitative research (interviews with school administrators and teachers, also the RESAs’ staff). QUAN results identified where and how frequently administrators sought information, whereas QUAL findings “revealed surprising variations in the ability of school administrators to select outside agencies for new information” (p. 638). This divergence led to conduct an additional survey “to see how frequent these modes of contact were for different categories of school personnel” (p. 637). These additional QUAN results showed that school “administrators received considerably more services from their RESA than did teachers” (p. 637). They provided details about differences between school administrators and teachers, which were not given by QUAL findings (see quote below).

In this example, general patterns of assistance seeking were described through analysis of the quantitative data. By turning to the qualitative data, a whole new perspective was revealed. Two very different approaches for using outside assistance agencies were discovered that have important implications and create new insights for the way these agencies recruit and retain school districts as clients (p. 639). (...) Initiation: The [second] survey data thus elaborated the interview data, providing a richness of detail about differences between teachers and administrators that the qualitative data alone could not provide (p. 637).

In another example, Taneja (2016) studied the effect of argumentation in science class on students' motivation. QUAL findings suggested teachers successfully facilitated argumentation to increase student engagement. In contrast, QUAN results suggested students' engagement (measured by the Student Motivation Toward Science Learning scale) showed improvement for only one learning strategy. There was no corroboration. Thus, they concluded that initiation could be a solution to this divergence. In future research, "expanding the time over which students respond to motivation survey [...], and probably collecting and analyzing changes in motivation within different contexts of argumentation [...] will provide greater validity" (p. 181). In this example, initiation was mentioned, but not performed.

In the above-mentioned CME study (Pluye et al., 2013), initiation was also used. Some divergences between QUAL and QUAN data led to initiate a new research cycle. Some QUAL data suggested that the IAM questionnaire item "I recalled something" was not always clear from the respondents' perspective. As shown in the vignette on "Testing for multiple myeloma," MD08 rated "I recalled something," and said that they were "to make sure that there wasn't something that I had forgotten" (interview). This, among other justifications, led us to conduct a mixed methods validation study for the delivery of educational material (ecological and logical content validation) (Badran et al., 2017). In the QUAN component, participants were 5596 physician members of the Canadian Medical Association who used the IAM (234,196 ratings collected in 2012). The relevance of IAM items with respect to their main construct was calculated using descriptive statistics (relevance ratio R). In the QUAL component, the representativeness of IAM items was evaluated by 15 family physicians (semi-structured interviews). QUAN and QUAL results were juxtaposed in a table, discussed with experts, and integrated. As a result, the item "I recalled something" was replaced with another item: "I was reminded of something I forgot."

Conclusion

The richness of MM research lies on its capacity of integrating qualitative and quantitative evidence. This integration requires to deal with convergence and divergence. This chapter provided definitions of what are convergence and divergence as well as illustrations of how they can be handled within three main dimensions: scientific worldviews, literature reviews and primary research. It is hoped that readers will find this chapter useful to address upstream challenges of integration in mixed methods research and will further pursue its conceptual development.

Specifically, implications for educational researchers are threefold. With regard to worldviews, our recommendations can help students and researchers handle worldview-related tensions that can occur between mixed methods research team members. We suggest that members describe worldviews at play, then select an appropriate combination of worldviews (a-paradigmatic, substantive theory, single worldview, multiple worldviews, complementary strengths, and dialectical pluralism). Regarding mixed studies reviews, we suggest using a synthesis design (either convergent synthesis designs or sequential synthesis design) and handle convergences and divergences using different strategies such as sensitivity analysis and subgroup analysis. Finally, with respect to divergences between QUAL and QUAN data and results in primary mixed methods research, we suggest students and researchers look for divergences, and apply the proposed strategies when needed (verification, reconciliation, and initiation).

Introduction and background

Mixed methods research has been investigated from various perspectives by many authors. To summarize some of their definitions, mixed methods research is a deliberate blending of quantitative and qualitative methods, an ever-growing approach. Some authors perceive it to be a win-win approach with the best features of both worlds at the researcher's fingertips (Saldaña, 2015, p. 56). Saldaña and Omasta (2018, p. 159) build on this statement, affirming that the "intentional blending of qualitative and quantitative data collection and analyses for studies will benefit from the combined outcomes." Put differently, O'Reilly and Kiyimba (2015, p. 86) state that the fundamental claim of the mixed methods community is that the use of two or more methods within a single study increases the confidence in the findings, this is especially helpful within educational contexts where the school system itself is a subsystem within a much broader societal and indeed global system. In education we attempt to make sense of the system structures, and the interrelationships, as these are the key factors in the system, in understanding how these affect one another, sometimes in obvious but often non-obvious ways, change in the system is more likely (Senge, 2006). It is here that using mixed methods research becomes essential. The rationale of this type of research has been the ability to compensate for any weaknesses in a single research design, and when considering the education system this is an important consideration. Furthermore, integrating two different methods allows the researcher to obtain a more rounded and complete set of results, thus making the most of the complementary strengths of both quantitative and qualitative approaches. Therefore, mixed methods research aims not to replace either of the two approaches but to draw upon their strengths and minimize any limitations.

In this chapter, we privilege the notion of thinking qualitatively in the context of mixed methods research, which means, according to Saldaña (2015, p. 4–5), that researchers purposefully adopt different lenses, filters, and angles as they inquire into social life to discover new perceptions and cognitions about the phenomenon they are researching. Thinking qualitatively means acknowledging that not everyone thinks the same as researchers do and the ability to see things from the perspectives of others is essential in the search for understanding. Saldaña (2015) further argues that thinking qualitatively is a heightened awareness or metacognition, which means thinking about how the mind and heart work by analyzing data and reflecting on life (p. 4–5). Metacognition is not just about thinking how to think but knowing how to know. It is a hyper-awareness within social environments for observing sensory details and interpreting subtexts from people's words and actions. Thinking qualitatively is pondering the nuances of the data from data collection and data analysis. In this chapter, we first highlight the theoretical implications of privileging qualitative methods. We then discuss, from a methodological perspective, the importance of analysis components of mixed methods designs and how qualitative data can be transformed to add value to inferences drawn. The role of qualitative research in the conceptualizing phase of a mixed methods study is discussed, followed by a methodological discussion drawing on the analysis component of designing a mixed methods study. For each of these sections, an exemplar is used to highlight key aspects related to the theorizing of mixed methods studies. These exemplars were chosen for the purpose of highlighting how qualitative research can be highlighted and play a prominent role in design decision making.

Theoretical implications of privileging qualitative methods in mixed methods research design

If research is to be transformative, we need to reflect more critically on whose voice informs our research focus and research design (Mertens, 2017). There is a strong and established argument that without centering the voices of specific communities in the policies and programs that are directed at supporting and improving their health and well-being, the efforts made by policymakers to promote positive life outcomes will fail (Ford et al., 2003; Gaunle and Adhikari, 2010; Wallerstein and Duran, 2006). The same can be said in an educational context, where education plays an important role in the achievement of not only economic life

outcomes but also psychosocial life outcomes (Fernandez, 2019). Given the role of research in informing programs and policy in education, how research is conducted and how communities of interest are included is key, if not a critical, concern. When research findings more accurately reflect and account for the priorities of specific population groups, together with their lived realities, services and policies will be better able to support intended outcomes. Furthermore, when we integrate the perspectives of communities into what we research and how we do research, our research findings will be more closely aligned with their priorities and experiences (Kanáiaupuni, 2005; Krenichyn et al., 2007). In this way, the impact and success of programs and policies in education based on such research and related data will be significantly improved.

As researchers, we bring our substantive focus to our work. However, we often generate specific research questions and make related research design decisions based on our knowledge within this broad focus. This course of action does not guarantee that we account for the more immediate concerns facing school communities or particular population groups. Thought of differently, while we may be asking interesting and even good research questions, at best, these questions may be irrelevant given the lived experiences of those school communities we are working to understand. At worst, however, we may be generating research findings that reinforce discriminatory and oppressive practices (Lather, 1991; Mertens, 2021). Ignoring the self-determining nature of the individuals being studied raises questions about the ethics and validity of our work. As argued elsewhere (Liebenberg, 2009, p. 444), “If, ... the very basis of our research that is the questions asked in the research setting are based in existing “knowledge” formulated by dominant voices, how valid then is the data we analyze, and by extension, the findings of our research?” Strategically situating qualitative methods in research design and privileging the data from these methods better ensures that the research foundations are relevant to communities. This is especially true as demonstrated by Scherman and Liebenberg (2021) in how the instrument development process can be strengthened by privileging qualitative data in the process.

Similarly, and especially with quantitative research, we ordinarily draw on existing and privileged knowledge (i.e., published academic research) to make sense of research findings. Potts and Brown (2015, p. 19) explain that “knowledge is produced through the interactions of people, and as all people are socially and politically located ..., with biases, privileges, and differing entitlements, so too is the knowledge that is produced socially located and political.” Ironically, large-scale quantitative findings can be more richly explained by the lived experience brought to light by qualitative data (see, for example, the work of Munford and Sanders, <https://www.youthsay.co.nz/>). Asking school communities to comment on quantitative findings using qualitative approaches provides more accurate explanations of particular statistical results and what they mean to people and their daily lives. In addition to aiding in our understanding of statistical results, as researchers, we should also be mindful that while such results may provide crucial information on patterns in population education, health and behavior, for example, on their own, they cannot account for the complexity of people’s lives. Quantitative research results cannot necessarily explain why we see distinct patterns or what these patterns mean in real-life terms. The impact of such results is then significantly reduced, both in terms of policy and theory. Again, integration of qualitative approaches intended to illuminate the lived experience of quantitative results would contribute insights critical to effective policy and practice knowledge.

Collectively, research findings are of greater relevance to the populations of interest when qualitative research has been used intentionally to scaffold quantitative research design and explain quantitative results as has been illustrated by Scherman and Liebenberg (2021). Challenging dominant approaches to research that privilege quantitative research (Denzin, 2012), by amplifying the notion that knowledge is socially constructed, allows us to draw attention to the fact that while quantitative approaches can indeed provide important measurements of critical social issues, complex causes and understandings of these issues may remain unexamined (Potts and Brown, 2015). These methodological considerations reflect ontological and epistemological concerns regarding knowledge and how we create it (Potts and Brown, 2015). The argument is not whether we should be doing mixed methods research or, better, qualitative versus quantitative. The issue is, how do we integrate methods and acknowledge related data to produce research findings and theoretical models that support social change? These considerations are related to theoretical and social research concerns.

Hesse-Biber (2010b) reminds us that central to qualitative research is the assumption that reality is socially constructed and contextually informed. Relatedly, methods can be grouped into constructivist-interpretive, critical (Marxist, emancipatory), and feminist theory. Of importance to the argument we present in this chapter is that collectively, these approaches emphasize that knowledge is constructed, embedded in power structures that privilege some voices and marginalize others. These structures are best challenged by understanding lived experience. At its very heart, qualitative research intends to address issues of social injustice. Accordingly, theory development emerging from qualitative research needs to honor this intent. Intentionally privileging qualitative research methods within mixed methods studies should therefore align with these theories. Hesse-Biber (2010b) further explains that mixed methods studies informed by qualitative approaches enhance and achieve this in various ways. First, it augments the representativity and generalizability of findings stemming from the research and enhances the validity and reliability of these findings overall. Additionally, qualitative approaches can explore contradictions found in quantitative data, while quantitative approaches can test the validity of qualitative findings in a broader population. Finally, qualitatively driven mixed methods studies can enhance our understanding of the research question and related findings and provide convergence in findings using triangulation.

The role of qualitative research in conceptualizing a mixed method study

The previous section focused on the theoretical implications for the research design when privileging qualitative approaches for mixed methods research. In this section, the implications for practice and conceptualization are discussed, including a quick

tour of the use of analysis software in this context. Much has been written about mixed methods analysis and the use of computer-assisted qualitative data analysis software for mixed methods research (Smit, 2021). However, less is said about the design of mixed methods research and privileging qualitative approaches from the outset and incorporating analysis software.

A decade ago, Hesse-Biber (2010a) wrote prolifically about the focus on qualitative approaches to mixed methods research (p. 16) and argued for a move toward interdisciplinary scholarship, broader theoretical lenses, and social change. She discussed an essential distinction between qualitative methodologies and qualitative methods, explaining that qualitative methodologies include qualitative and quantitative methods (p. 17), which shapes the design decision. A few years later, Plano Clark and Ivankova (2016, pp. 198–202) offered a helpful table of prominent philosophies for mixed methods, giving a clear overview of the epistemological and ontological assumptions and mapping these philosophies and assumptions to accompanying scholarly writings.

Many scholars followed Hesse-Biber (2018), Onwuegbuzie and Johnson (2021), Plano-Clark and Ivankova (2016), which is not an exhaustive list of mixed methods scholars. Scholars such as Leavy (2014) and Tracy (2020) have also added educational value to the nuanced complexity of privileging qualitative research in mixed methods research. Ritchie et al. (2014, p. 45) in this regard remind us “when using qualitative and quantitative research in combination it is important to recognize that each offers a different way of knowing about the world, and it should not be expected that the evidence generated from the two approaches will replicate each other. Rather, the benefits of mixing methods may result from the ability of each method to add to a more nuanced picture of complex social phenomena.”

Considering a research design, Tracy (2020, p. 27) invites researchers to “ask what types of methods are best suited for the goals of the research project?” She elaborates, “many people consider methods to be akin to tools. Like a hammer is a better tool than a screwdriver for banging a nail into a wall, qualitative methodology is better than a quantitative methodology for richly describing a scene or understanding the stories people use to narrate their lives” (p. 27). The toolkit idea or using what works in the educational context has been a prominent thought in mixed methods research, especially in relation to a pragmatist point of view (Tashakkori and Teddlie, 1998; Teddlie and Tashakkori, 2003). Furthermore, fieldwork is especially worthwhile for understanding behaviors and interactions that people do not talk about – either because these phenomena are unconscious, hard to remember, embarrassing, or simply mundane. When people describe the unique value of qualitative, compared to quantitative research methods, they often point to the ability of qualitative research to provide insight into why and how questions. Such research questions seek meaning qualitatively and often pursue the implicit or the unspoken if people cannot put into words what is important to them or why they acted in a certain way (Tracy, 2020, p. 100).

The research question shapes the research design and methodology. The concepts of research design and methodology are often used interchangeably. For this chapter, we discern between these two constructs as follows: research designs can also be considered as approaches or strategies, for example, case study designs, action research, phenomenology, ethnography, or narrative inquiry. The research methodology section covers sampling, data collection, data analysis, and matters of rigor and quality. Depending on what the research question wishes to answer and the decision to employ a mixed methods study, the researcher needs to decide how and why qualitative approaches are privileged and in what way.

When the research rationale addresses complex or cultural activities where the daily processes and activities are explored (Nastasi and Hitchcock, 2016), qualitative approaches will suitably design mixed methods research. The strength of qualitative research lies in its holistic, contextual, co-constructed interpreted meaning, including the reinterpretation of quantitative data. These multiple interpretations offer theoretically compelling suggestions for the research design and methods (Motulsky, 2021). Accordingly, qualitative methods is an umbrella concept that covers interviews (group or one-on-one), participant observation (in person or online), and textual analysis (paper or electronic). Such methods can include research in the field, a focus-group room, an office, or a classroom. Qualitative methods need not include long-term immersion in a culture or require a holistic examination of all social practices. One of the most common ways qualitative research is understood is through comparison with critical features of the quantitative method, where quantitative research can transform data into numbers, including conversations, actions, media stories, facial twitches, or other social or physical activity (Tracy, 2020, p. 26).

Tracy (2020, p. 378) also offers a word of caution: “Qualitative researchers face challenges in terms of securing grants, as many governmental agencies assume that the only sound research is objective, scientific, and quantitative. And even though funding agencies are increasingly providing grants to mixed methods researcher teams, qualitative methods are still grossly underrepresented in funding dollars. Grants typically reward research that is framed as efficient, immediately useful, and easily communicated. This marginalizes qualitative research – much of which is long-term, inconclusive by design, philosophical, and artistic. Furthermore, writing grant proposals takes a lot of time and energy and usually requires multiple submissions before they are funded. It is important to weigh carefully the pros and cons of spending time on writing a grant proposal when that precious time might instead be devoted to conducting and publishing a smaller unfunded study.”

Methodological implications for the research design

Mixed methods research has established itself as a third methodological paradigm (Collins et al., 2012). Scholars are, however, still grappling with some issues. One issue is rethinking how qualitative research could be featured more prominently. As a result, a systematic understanding of the context becomes possible (Nastasi and Hitchcock, 2016). Also, qualitative richness in terms of meaning and understanding that people bring to phenomena cannot be replicated in quantitative research. Hesse-Biber (2018) as well as Morse and Cheek (2015) clearly state that while qualitative research brings richness to the mixed methods study, the focus

on methods means that empirical or rather quantitative methods are prioritized from the design phase. It should also be noted that the design decisions are then extended to all aspects of the project from the theoretical perspective that links a research problem and approach to the particular method or methods of data collection and analysis.

Furthermore, qualitative research is a powerful tool for theory and model development (Leech and Onwuegbuzie, 2007). In many research projects, these are vital elements, and within the repertoire of qualitative techniques, several choices will promote rigor and yield credible findings (Nastasi and Hitchcock, 2016). Our point of departure is, as described by Bazeley (2013, p. 1) that “analysis is laid on the foundation of our understanding of how the world works, what it is (ontology); and how we understand and learn about the world and especially about the world of people (epistemology) ... although these foundations may remain implicit rather than explicit, thinking about them sharpens and enriches ... our understanding.”

There are several analysis techniques within qualitative research which would be appropriate in terms of educational research, although the dominant approach in educational contexts would be categorizing and theming verbatim data. The process entails condensing data into a theme that has emerged from the categorization data. However, other techniques are used to extend the role of qualitative data in mixed methods designs. Of course, the aim of incorporation of such data speaks to what Miles et al. (2014, p. 11) call “richness and holism, with strong potential for revealing complexity.” Given that analysis is not as well expanded upon, a brief overview is provided of the seven techniques described by Leech and Onwuegbuzie (2007) as the different techniques can be applied within a mixed analysis. When thinking about mixed methods analysis, a parallel approach may come to mind where data from the qualitative component of the study and the quantitative approach are kept separate and inferences are brought together but the data is not merged or converted. Cross-over or mixed analysis implies that one data form is transformed into another, quantitative data transformed to qualitative data or where qualitative data is transferred to quantitative data (Onwuegbuzie and Johnson, 2021).

In terms of data analysis specifically, there are various approaches that can be used as part of what Tracy (2020) would refer to as the toolkit. Leech and Onwuegbuzie (2008, p. 590) describe additional analysis techniques associated with a specific type of data (see Fig. 1). The most prominent analysis techniques, highlighted by Leech and Onwuegbuzie (2008):

- The first data analysis technique is constant comparison analysis, like what researchers would understand by theming data. The transcripts are read and chunked into meaning segments. The segment is then coded and compared with other codes. Similar codes are grouped under a theme.
- The second analysis technique is keywords-in-context, where the words are analyzed by comparing what comes before and after keywords. Keywords are identified as words that are either used frequently or used unusually.
- The third technique is word counts, where the number of times a specific word is used is counted, this type of analysis is generally used throughout the research process.
- The fourth analysis technique is content analysis, where the number of times a code is used is counted. The codes are usually produced deductively.
- The fifth analysis technique is domain analysis. Domain analysis is used where the researcher would like to identify larger units of cultural knowledge, where symbols represent a way of communicating cultural meaning. Domain analysis is followed by taxonomic analysis, where a classification system is developed to understand the relationships among domains. The type of analysis described by Leech and Onwuegbuzie (2007) is componential analysis, where attributes associated with cultural symbols are identified.

In terms of mixed methods, the rationale for including a qualitative component would be to improve quantitative designs, optimize sample sizes, instrument fidelity, treatment integrity, or maximize interpretations based on quantitative data (Leech and Onwuegbuzie, 2007). In mixed analysis, where qualitative and quantitative analytical techniques are used within the same framework (Onwuegbuzie and Johnson, 2021), researchers require competence in qualitative and quantitative analytical techniques. For this reason, researchers should also understand the range of analytical techniques and what can be accomplished. Of course, mixed analysis and cross-over analysis, as described earlier, would be appropriate in any mixed method study but is also highlighted in the article by Scherman et al. (2018). Creamer (2018) identifies five analytical procedures which may be appropriate in an integrated study where mixed analysis is used:

1. Blending: A variable, category, and theme created in one type of data is tested using another type of data or is created by combining qualitative and quantitative data.
2. Converting: Qualitative data are converted to quantitative data or vice-a-versa.
3. Extreme case sampling: Identifying and selecting the extremes or outliers.
4. Cross-case comparison: Consolidating qualitative and quantitative data to test or expand qualitative or quantitative derived themes.
5. Meta-inference: Link, compare or contrasts inferences generated by qualitative and quantitative strands.

A practical example of mixed analysis where qualitative data are highlighted can be found in Scherman et al. (2018), where a mixed monotype analysis in the article where qualitative data are quantitized (Onwuegbuzie et al., 2007; Onwuegbuzie and Johnson, 2021). Scherman et al. (2018) further highlight cross-validation where qualitative and quantitative analyses were used to examine the exact dimension of the research problem. The goal was to illustrate how a framework for developing causal pathways can be built to identify possible ways of working with parents, based on the people’s experiences (Dixon-Woods et al., 2005).

Fig. 1 Different analysis techniques for data sources (Leech and Onwuegbuzie, 2008, p. 590)

Bazeley (2012) states that integration can range from discussions of the different phases identified in the research to synthesizing, combining, or converting data from one form to another. Thus, for the analysis described in the article by Scherman et al. (2018), individual models of expectations and a general model were postulated. The article by Scherman et al. (2018) further shows that while the individual models are explained and nuanced in the qualitative data, a general model from the qualitative data could be put forward using quantitative analysis. Qualitative and quantitative approaches were required to understand the phenomenon (Bazeley, 2012), making the most of the collected data.

The article by Scherman et al. (2018) also described a dual analytic approach, and data were analyzed in one form and then manipulated into another form (Bazeley, 2012). This involved quantifying the qualitative codings, which adds to detecting and describing patterns in the data. However, given that sample sizes are typically small, it was essential to use the appropriate statistical analysis. The article thus shows how nonparametric can be used when the sample sizes are too small to meet the requirements of parametric statistics.

An additional consideration which is important is that of methodological norms. Scherman et al. (2018) show how norms for qualitative and quantitative research can be adhered to (member checking for qualitative research, content-related validity, and statistical conclusion validity for the quantitative component). Several mixed methods legitimization types has to be made explicit. The inside-outside legitimization is highlighted in which the researchers present and appropriately use the insider's and observer's view to deepen understanding, description, and explanation. Conversion is another prominent legitimization type, which is the focus of the article by Scherman et al. (2018), in which qualitative data is quantified to yield meta-inferences. Multiple validities as mixed methods legitimization are also included and understood as the extent to which addressing both quantitative and qualitative legitimization yields high-quality meta-inferences (Collins et al., 2012).

It is vital to be cognizant that answering the research question requires an appropriate means for making sense of data. The primary processes for analyzing quantitative data are descriptive and inferential statistics, while qualitative data analysis generally

relies on coding (O'Dwyer and Bernauer, 2014, p. 35). Whether we analyze numbers of words, we need appropriate processes and tools to make meaning from these data, and this usually involves some data reduction using statistics and coding.

The last thought relates to using software for qualitative research in mixed methods research. A few scholars have written about ATLAS.ti, NVivo, MAXQDA, QDA Miner, and Dedoose, (see Onwuegbuzie and Johnson, 2021). While these programs were developed initially for qualitative data analysis, scholars have reimagined these programs, together with new add-ons by the developers to include mixed methods analyses. This is indeed an exciting development, and researchers can now benefit from this computer assisted qualitative data analysis software (CAQDAS) given the variety of data types that can be imported or added to the software. Smit (2021, p. 331) wrote explicitly about the use of ATLAS.ti 22 for mixed analysis, which now is in version 22 with even more features supporting mixed data analysis. Also, the work by Saldaña (2021) fits comfortably in the use of software, discussing qualitative and mixed methods coding strategies. Smit (2021, p. 333) also elaborates on the use of ATLAS.ti for the literature review, which is seen as qualitative text analysis, using qualitative data analysis strategies (Onwuegbuzie and Leech, 2021). Literature reviews are essential for qualitative and mixed methods studies, and software such as Mendeley and Endnote interface comfortably with ATLAS.ti. Hesse-Biber (2010a) has reminded us back in 2010 how the introduction of CAQDAS has enabled researchers to begin to transform qualitative and quantitative data to suit their methodological purposes, a design consideration, which we cannot ignore.

Concluding thoughts

Mixed methods research is complex by its very nature (Poth, 2018). The same can be said of education and education systems. Very often, single studies cannot account for the complexity of the education system but with mixed methods research, a fuller picture can be provided. Furthermore, by privileging qualitative methodology, the educational context can be studied in a more meaningful way. In this chapter, we have highlighted key issues related to theorizing and making methodological decisions where qualitative methods can be prioritized. Hesse-Biber (2010a, p. 24) stated eloquently, "mixed methods can be an exciting process that might open our eyes to new realities and levels of understanding, but such a research design must be utilized only with the certainty that it will aid in advancing our theoretical understanding and not detract from our existing methodologies." We concur that "a qualitative approach privileges qualitative methods, with quantitative methods component playing an auxiliary role in a mixed methods framework (Hesse-Biber, 2010a, p. 64).

Introduction

Quantitative and qualitative methods can be mixed at any stage of the research process: during data collection, data analysis, and/or data interpretation (Greene, 2007; Tashakkori et al., 2021). In many mixed methods research studies, mixing typically occurs at the level of interpretation whereas mixing is less common during data collection and data analysis (Onwuegbuzie and Hitchcock, 2015; Onwuegbuzie et al., 2009). When planning a mixed methods research study, it is important to think through where the mixing will occur (Collins et al., 2006), and to ensure that the mixing assists in answering the research questions (Onwuegbuzie and Leech, 2006). Two places to mix qualitative and quantitative methods in a mixed methods study are during the sampling procedure and data collection.

In a social science research study, sampling is the process where cases/participants/units are drawn from a larger population to participate in the study (Johnson and Christensen, 2020). It is important that the group selected matches the population and/or includes participants who can provide information or insights to answer the research question(s). In a mixed methods study, there are a myriad of sampling schemes available. After sampling, these cases/participants/units are invited to participate in the research study and information is collected from them (i.e., data collection is conducted). Yin (2006) stresses that quantitative and qualitative data collection methods need to ensure the data overlap and/or complement one another. This is a major challenge in most mixed studies, but many accomplish this via conceptual frameworks that tie the over-arching concepts together (Wheeldon, 2010). To better understand sampling and data collection in mixed methods research studies, each are outlined below.

Sampling in mixed methods research studies

Sampling is defined as “the process of selecting a subset or sample unit from a larger group or population of interest” (Collins, 2010, p. 356). In mixed methods research studies sampling is an important step as it can impact the types of statistical analysis (i.e., quantitative analysis), strengths of the transferability of findings (i.e., qualitative analysis), and inferences (i.e., mixed analysis) that can be drawn (Collins et al., 2007; Teddlie and Yu, 2007). Sampling in mixed methods studies involves “two distinct yet interrelated decisions: decide on the strategy to select the participants (i.e., sampling scheme) and decide on the number of participants (i.e., sample size)” (Collins, 2010, p. 354). Thus, sampling in mixed methods studies can be complex, with one or multiple types of sampling designs and with one or multiple samples (Collins, 2010). The samples can be nested (e.g., having one large sample and then sampling a smaller sample from the original sample), sequential (e.g., having one sample for the first phase of the study and another sample for second), or parallel (e.g., having one sample for the quantitative phase and another sample for the qualitative phase with the data collected at the same time).

Types of sampling schemes

In many mixed methods research studies, more than one type of sampling is conducted (Teddle and Yu, 2007). Traditionally, depending on the type of design (qualitative or quantitative), different types of sampling are conducted. In general, from a quantitative perspective, sampling is conducted through probability sampling and from a qualitative perspective, sampling is accomplished through purposeful sampling. Yet, this differentiation is artificial (Bernard, 1995; Guest et al., 2006): there are four types of sampling available for mixed methods researchers: (a) probability, (b) purposive sampling, (c) convenience sampling, and (d) mixed methods sampling (Teddle and Yu, 2007). Understanding each of these can assist the mixed methods researcher in choosing sampling schemes, thus probability sampling, purposive sampling, convenience sampling, and mixed methods sampling will be briefly described with an example from the extant literature where the type of sampling has been used.

Probability sampling

Historically utilized in quantitative designs, probability samples focus on using random sampling to find a group of participants that represent the population of interest. By using a probability sample, theoretically every person in the population has an equal opportunity to be sampled, which then enables the research to make generalizations from the sample to the population. When conducting probability sampling, before conducting the sampling procedure, the researcher assesses the approximate number of needed participants/units/groups by conducting a power analysis. Sampling is then conducted utilizing random sampling or a variant of random sampling [i.e., stratified sampling, cluster sampling, and sampling using two-stage or multistage probability techniques (Johnson and Christensen, 2020)]. Stratified sampling is when the sample is divided into groups based on a specific variable (e.g., area of town where they live) and then samples are drawn from the groups. Cluster sampling is

a two-stage probability sampling procedure that is especially useful when the population is spread out geographically and/or when there is no single overall list of individuals in the accessible population; individual participants within a given cluster are usually geographically grouped together; basic strategy is to first select specific clusters from the list of all clusters using a probability sampling method, then select all or randomly select a specific proportion of participants from the selected clusters.

Gliner et al., p. 484.

Finally, sampling using two-stage or multistage probability techniques is conducted by sampling in multiple stages. For example, in a two-stage sampling framework clusters may be selected (e.g., areas of town to be utilized in the research study) and then in stage two participants would be sampled from the selected clusters. Jensen et al. (2020) explored company's performance and CEO's transformational leadership skills using a random sample to select participants. From a publicly-listed set of US and European companies, 42 CEOs were selected.

Purposive sampling

A second type of sampling is purposive sampling (Mile and Huberman, 1994). When conducting purposive sampling, the researcher searches for participants that can provide unique or a depth of information (Maxwell, 1997; Sandelowski, 1995). With purposive sampling, based on theory and research question(s), a criterion/specific characteristic or parameters are defined to limit who is searched for in the participants. Purposive sampling is typically nonrandom, but it can be conducted via random sampling. Lawrence (2020) provides a good example of purposive sampling where they investigated "influential family factors for youth with learning and mental health concerns" (p. 166). In this study, two participants were purposively selected for the qualitative strand of the study. Their goal was to interview middle schoolers due to this age "reflects increasing academic demands and related distress at school (Feurer and Andrews, 2009), as well as heightened developmental patterns of internalizing problems" (p. 171).

Convenience sampling

Probably the most common type of sampling, convenience sampling is when an accessible sample and/or volunteer sample is obtained (Teddle and Yu, 2007). When using a convenience sample, the researcher does not select or choose who will participate. For example, if every person walking by a store is asked to complete a survey, this is convenience sampling. Simon (2020) provides an excellent example of convenience sampling in their study to investigate imposter syndrome experienced by Black women in a doctoral program in science, technology, engineering, and mathematics (STEM). Convenience sampling was utilized in this study after completing interviews of participants, "To substantiate the data collected from the analysis of the interviews, an 89 min focus group was held with a convenient sample of five students" (p. 190).

Mixed methods sampling

There are five types of mixed methods sampling (i.e., basic, sequential, concurrent, multilevel, and combination of mixed methods sampling). When using a mixed methods sampling scheme, participants/units/cases are selected utilizing both purposive and probability sampling. By using both types of sampling, the external validity and transferability of the inferences are increased (Teddle and Yu, 2007). McGill et al. (2020) provides an example of using mixed methods sampling. First, McGill et al. (2020) used purposive sampling to identify advisors at a major university. After collecting data from the purposively sampled advisors, these authors

used random sampling to select 10 participants to further interview. Thus, McGill et al. (2020) utilized purposive sampling and then probability sampling as a mixed methods sampling technique.

The many types of sampling are only tools, and these tools can be used interchangeably in qualitative, quantitative, and/or mixed designs (Onwuegbuzie and Leech, 2007). Based on this belief and utilizing the sampling identified by Patton (1990) and Miles and Huberman (1994), Onwuegbuzie and Leech (2007) outlined 24 sampling schemes that are available for mixed methods researchers. Table 1 presents the sampling scheme developed by Onwuegbuzie and Leech (2007) with a brief description of each as presented by Onwuegbuzie and Collins (2007).

Data collection in mixed methods research studies

What is unique about mixed methods research designs is that they are not limited by the type of data that researchers choose to collect (e.g., surveys, interviews, or observational data). Instead, the confines of data collection are procedural issues regarding how many samples are needed and when data is collected (Hanson et al., 2005). To outline the types of data collection processes available for mixed methods researchers, the following are delineated along with benefits and limitations of each: one sample, one time point; one sample, different time points; and different samples, different time points.

Table 1 Major sampling schemes in mixed methods research.

<i>Sampling scheme</i>	<i>Description</i>
Simple	Every individual in the sampling frame (i.e., desired population) has an equal and independent chance of being chosen for the study.
Stratified	Sampling frame is divided into sub-sections comprising groups that are relatively homogeneous with respect to one or more characteristics and a random sample from each stratum is selected.
Cluster	Selecting intact groups representing clusters of individuals rather than choosing individuals one at a time.
Systematic	Choosing individuals from a list by selecting every k th sampling frame member, where k typifies the population divided by the preferred sample size.
Multi-stage random ^a	Choosing a sample from the random sampling schemes in multiple stages.
Maximum variation	Choosing settings, groups, and/or individuals to maximize the range of perspectives investigated in the study.
Homogeneous	Choosing settings, groups, and/or individuals based on similar or specific characteristics.
Critical case	Choosing settings, groups, and/or individuals based on specific characteristic(s) because their inclusion provides the researcher with compelling insight about a phenomenon of interest
Theory-based	Choosing settings, groups, and/or individuals because their inclusion helps the researcher to develop a theory.
Confirming/disconfirming	After beginning data collection, the researcher conducts subsequent analyses to verify or contradict initial results.
Snowball/chain	Participants are asked to recruit individuals to join the study.
Extreme case	Selecting outlying cases and conducting comparative analyses.
Typical case	Selecting and analyzing average or normal cases.
Intensity	Choosing settings, groups, and/or individuals because their experiences relative to the phenomena of interest are viewed as intense but not extreme.
Politically important case	Choosing settings, groups, and/or individuals to be included or excluded based on their political connections to the phenomena of interest.
Random purposeful	Selecting random cases from the sampling frame and randomly choosing a desired number of individuals to participate in the study.
Stratified purposeful	Sampling frame is divided into strata to obtain relatively homogeneous sub-groups and a purposeful sample is selected from each stratum.
Criterion	Choosing settings, groups, and/or individuals because they represent one or more criteria.
Opportunistic	Researcher selects a case based on specific characteristics (i.e., typical, negative, or extreme) to capitalize on developing events occurring during data collection.
Mixed purposeful	Choosing more than one sampling strategy and comparing the results emerging from both samples.
Convenience	Choosing settings, groups, and/or individuals that are conveniently available and willing to participate in the study.
Quota	Researcher identifies desired characteristics and quotas of sample members to be included in the study.
Multi-stage purposeful random	Choosing settings, groups, and/or individuals representing a sample in two or more stages. The first stage is random selection and the following stages are purposive selection of participants.
Multi-stage purposeful	Choosing settings, groups, and/or individuals representing a sample in two or more stages in which all stages reflect purposive sampling of participants.

^aRepresent random (i.e., probabilistic) sampling schemes. All other schemes are non-random.

One sample, one time point

Some mixed methods designs involve data that is collected from a single sample (i.e., the same people) at a single time point. Typical examples of this include: (1) Conducting a survey with quantitative and qualitative items and (2) Conducting an interview with a scale or survey items asked within the interview protocol or in a separate survey taken at the same time as the interview. In this design the mixing takes place by connecting the two datasets via a sampling framework (Fetters et al., 2013). Steed et al. (2021) provides from the extant literature an example of a single sample at a single time point: the authors conducted a concurrent equal status fully mixed-method study (Leech and Onwuegbuzie, 2009) in which the participants completed an online survey that included both qualitative and quantitative data. Thus, quantitative and qualitative data were collected from a single sample at the same time point.

Benefits

The major benefit to this method of data collection is in saving time and money (Leeuw and Hox, 2008). Collecting data all at once in one time point is simply faster and more efficient for the researcher. Almalki (2016) also notes this technique tends to yield less data making it easier for researchers to manage and merge, which creates an efficient mixed method design.

When both types of data are collected together it offers the researcher more opportunities to mix the data (Leeuw and Hox, 2008). Data can be analyzed together using one to inform the other. One type of data could be converted and used within analyses of the other via quantitizing or qualitzing the data. Quantitizing is defined as “the process of converting [qualitative] data into numbers that can be statistically analyzed” (Tashakkori et al., 2021, p. 35). On the other hand, qualitzing is defined as “the process whereby [quantitative] data are transformed into narrative data that can be analyzed qualitatively” (Tashakkori et al., 2021, p. 35). Data can also be analyzed separately and mixed in interpretation through methods like triangulation. This is also more flexible as it is not hindered by which data was collected first.

This design also tends to be easy for participants since data is collected all at once and in a manner that feels natural for participants to answer (Driscoll et al., 2007). Additionally, it has been considered good practice to ask personal information in face-to-face, private settings to build relationships and trust with participants (Gliner et al., 2017) and is standard practice to ask sensitive, confidential information in either interviews or via surveys (Leeuw and Hox, 2008). This design allows for both methods to be collected at once.

Limitations

In comparison to the other methods, this design does not include an opportunity to follow up on the learning from one set of data based on the other dataset. Another major limitation of this design is there are measurement differences between the qualitative and quantitative data that are not easily addressed. Meaning, it is challenging to treat the qualitative findings equally to the quantitative findings as they are measured differently (Yin, 2006). Finally, this design encourages smaller sample sizes as most research teams are not able to collect qualitative information on a large sample. This create validity challenges for studies who are trying to generalize findings to a large population (Ihantola and Kihn, 2011).

One sample, different time points

Many mixed methods designs use a single sample but collect one set of data at one time and then follow-up at a later date with a same sample or a smaller portion of the original sample. Two classic examples are: (1) conducting a survey then following up with interviews from participants drawn from the survey results, and (2) Conducting focus groups with an organization and then sending a follow up survey. Here again, mixing takes place via a sampling framework (Fetters et al., 2013) and also by allowing one dataset to inform the other in analysis and interpretation stages (Onwuegbuzie et al., 2007). McGill et al. (2020) is an example of one sample at different time points. In this sequential explanatory mixed methods study, the authors sampled 57 full time academic advisors who were participating in a professional development (PD) program and asked them to provide information on what they learned from the PD. After analyzing these data, the authors wanted to investigate further, so they randomly sampled 10 participants from the initial 57 academic advisors. These 10 participants were then interviewed to better understand how the PD affected their advising.

Benefits

The major benefit of these data collection design is that one set of data can be analyzed to inform the second set of data (i.e., sequential mixed methods designs). This also allows for the qualitative data to help explain and validate the quantitative findings or vice versa. When qualitative data is collected first it can inform quantitative tools and help generate stronger hypotheses for the quantitative analysis (Fetters et al., 2013).

Limitations

The foremost disadvantage of this design is the time needed to design and conduct separate studies (Driscoll et al., 2007). Recruitment of participants can be challenging as you are limited in the second data collection by the first sample (Almalki, 2016). Since the data is collected from the same sample, quantitative sample size can be limited by the qualitative data collection capabilities (e.g., you might collect 200 survey responses but not be able to conduct 100 matched interviews). Due to the sequential design,

there is potential for temporal validity concerns where the time between data collection can become a confounding variable (Leeuw and Hox, 2008). For example, if one data set was collected before a major, unexpected event occurred, will the second set of data still be valid based on the first one's findings?

Different samples, different time points

An incredibly popular method of data collection in mixed designs is to collect one sample at one time point that is used to inform data collected from second sample at a second time point. Sequential designs are a great example where mixing occurs in the analysis and/or interpretation stages as one dataset influences the next. Examples include: (1) Interviews and focus groups are used to create constructs and items for a larger survey, and (2) An anonymous survey is given with focus groups conducted after to explore/explain survey findings which are pulled from the sample population, but not necessarily the same sample. Lawrence (2020) provides a good example different samples at different time points. In this study, the quantitative phase was conducted first with a data from 24,915 parents. To better understand the quantitative results the qualitative phase was then conducted with two families who were purposively selected.

Benefits

Like the previous design above, the benefit to this design is having one dataset to help design and/or explain the other dataset's findings. Unique to this design is that the sample is not limited for the quantitative data collection by the sample size restrictions in the qualitative data collection which makes external validity arguments stronger (Ihantola and Kihn, 2011).

Limitations

Again a major limitation for sequential designs is the time and resources needed to conduct two studies. Temporal validity concerns occur here too depending on how much time occurs between sampling. A unique challenge to this design is directly linking the datasets (Driscoll et al., 2007) together in a logical manner so the studies are truly mixed and not simply parallel or separate studies (Yin, 2006). Along the same line is the challenge is the two datasets may not be equal, even if pulled from the same population, which raises validity and reliability concerns (Ihantola and Kihn, 2011).

Conclusion

In the process of conducting a mixed methods study, two important steps are sampling and data collection (Collins et al., 2006). Using appropriate sampling techniques in mixed methods studies has multiple implications for researchers in education and beyond. Utilizing appropriate and well-thought through sampling and data collections methods, whether quantitative, qualitative, or mixed, can increase the legitimation, generalizability, and/or trustworthiness of the results (Onwuegbuzie et al., 2010). Furthermore, being thoughtful regarding the data collection procedures can ensure the data collected will answer the research questions (Onwuegbuzie and Leech, 2006). Paying close attention to these steps can increase the rigor of mixed methods studies.

The integration challenge in mixed methods research

Mixed methods research (MMR) is defined as the process of combining different methodological approaches—usually labeled as qualitative and quantitative—within one overarching study. Many different types of combinations are possible at various steps in the research process and for a number of purposes. In simplistic terms, the key argument for MMR is that multiple investigative strands increase or improve the understanding of a phenomenon (Creamer, 2022). After debates on paradigms and compatibility in the early phases of the “mixed methods era” as well as the development of typologies for MMR designs, the focus has shifted toward more practical strategies of working with data (Baur et al., 2017; Bazeley, 2010). Within the MMR community, there is growing sensitivity regarding the practical and conceptual challenges in meeting the expectations of MMR to gain synergies and complementarities by using both qualitative and quantitative data methods. As expressed by Bryman (2007, p. 8), “the key issue is whether in a mixed methods project, the end product is more than the sum of the individual quantitative and qualitative parts.” This goal can only be achieved through integration.

Data integration means that different sources of data are used to construct a joint product through the application of various analytical strategies (Li et al., 2000). These strategies deal with elements in the source data in different ways, but each strategy aims for the same research objective. Integration asks about the relatedness of different data, or the degree of “mutual illumination” (Bryman, 2007, p. 8), and it occurs to the extent that different data elements become interdependent in the course of reaching a theoretical or research goal (Bazeley, 2010). The product of integration is more than the sum of its constituent parts (Fetters and Freshwater, 2015)—it is the creation of a new whole (e.g., Onwuegbuzie and Hitchcock, 2019). In contrast, *data combination* is an “additive process” in which different types of data are mixed, but the results can still be traced back to each of the original data sources.

Many researchers consider integration to be the hallmark of mixed methods research (Moseholm and Fetters, 2017), as well as “the heart and soul of mixed methods research” (Guetterman et al., 2020, p. 430). Despite integration having great potential in MMR, it often remains underdeveloped and undertheorized (Bazeley, 2010). Qualitative and quantitative analyses are frequently conducted separately, and the results are only integrated in the overall interpretation and meta-inferences. Thus, addressing the “integration challenge” (Fetters and Freshwater, 2015) is the key challenge for the future of MMR.

While integration can occur in all steps of a research design, it seems to be particularly relevant but also the most challenging during data analysis (Onwuegbuzie and Combs, 2010). In this contribution, I focus on data analysis in MMR, specifically with integration in mind. Integrative analysis can foster better, more comprehensive results and a deeper understanding of a phenomenon. However, methodological and conceptual challenges, such as different sample sizes, violation of assumptions for statistical tests, and integrating data, highlight the need for innovative strategies (Fakis et al., 2014; Niglas et al., 2008) to enable achieving the full potential of MMR. A scarcity of good examples and the lack of literature about the research process and techniques of integration (Woolley, 2009) make integrative data analysis strategies a fruitful area for further research.

In the following section, I will provide an overview of the specificities of mixed methods data analysis. Afterward, I will present different data integration strategies and illustrate them through the use of an empirical example. In the conclusion, I will summarize and reflect on data integration to show that the distinction between qualitative and quantitative data is oversimplified. This dichotomy can hamper integrative thinking and practice.

Mixed methods data analysis

Generally, data analysis fulfills the functions of reducing and organizing raw data to make the information manageable. Data analysis can reveal patterns of relations, connections, trends, and differences. *Mixed methods data analysis* covers qualitative and

quantitative analytic strategies under the same or a similar framework and entails the analysis of qualitative *and* quantitative data. The data could stem from sequential, parallel, or iterative processes in one or more phases of data collection (Onwuegbuzie and Hitchcock, 2015). Further, mixed methods analyses can also be performed sequentially, in parallel, or iteratively with different objectives and purposes (see for example Vogl, 2019). The analyses could consist of multiple steps or even strands. Usually, data from each strand are analyzed with “appropriate” methods (Creswell and Plano Clark, 2018). The interfaces (Creswell and Plano Clark, 2018) and the extent to which the qualitative and quantitative strands interact in the analysis depend on the research design and the research question.

Mixed methods analyses are not an end in themselves but must reflexively relate back to the research question. The research question determines how and to what extent different data are integrated during analysis and interpretation (Brannen and O’Connell, 2015). Researchers must have a clear vision of what “dynamic mixes they suggest or permit” (Sandelowski, 2000, p. 254) and to what end. The researcher’s vision shapes the combined use of qualitative and quantitative techniques and its purpose.

The *purposes of mixed methods analysis*, which are analogous to design and data collection in MMR, can include the following (Caracelli and Greene, 1993; Greene et al., 1989; Onwuegbuzie and Hitchcock, 2015; Schoonenboom and Johnson, 2017):

- *triangulation/corroboration/convergent validation*: results based on one method are confirmed by those gained through the use of another method (e.g., when qualitative typology building is compared with latent class modeling)
- *complementarity/analytic density*: qualitative and quantitative results are considered distinct but generate complementary insights that together create a bigger picture (e.g., when qualitative data add a more nuanced understanding of a phenomenon that is also assessed with quantitative measures)
- *development*: the analysis of one data type informs the generation of another (e.g., when a qualitative typology informs a classification for statistical analysis)
- *initiation*: the use of a first method sparks new hypotheses or research questions that can be pursued using a different method (e.g., when findings in qualitative data inform statistical modeling)
- *elaboration/expansion*: the use of one type of data analysis adds to the understanding gained by another (e.g., when quantitative data contain information that adds to qualitative data, such as some psychological measures complementing biographical analysis).

It is important to mention that these purposes are neither exclusive nor unalterably set at the beginning of a study; they can emerge as research progresses.

Integrative mixed methods analysis

After this brief introduction to MMR and mixed methods analysis, I will focus on integrative mixed methods analysis. Data integration in mixed analysis refers to finding relationships between different data such that a new whole is created. In the literature, different terms are used for relating various strands of mixed methods data: mixing, combining or connecting, and integrating and merging. Combining and connecting refers to an additive process in which the original source data can still be traced ($1 + 1 = 2$), while integrating and merging creates a new element to the data beyond the qualitative and quantitative sources ($1 + 1 = 3$; Fetters and Freshwater, 2015), or $1 + 1 = 1$ when the result of full integration cannot be distinguished into separate parts but becomes a new whole; e.g., Onwuegbuzie and Hitchcock, 2019). Data combination means that the types of data are largely independent, but for integration, the types of data are either highly or largely dependent on one another (van Velzen, 2016; Woolley, 2009). Mixing seems to be the most general and least consistently used term. Some researchers regard mixing as being synonymous with integration and merging (Johnson et al., 2017), while others view merging as a form of mixing (Collingridge, 2012). I suggest using the term mixing as an overarching concept that encompasses combination and merging/integration.

Integrated mixed methods data analysis not only involves the analysis of qualitative and quantitative strands—it also entails an analysis of the interaction between the two strands. This is consequential for the workload and required skills. Kuckartz (2014) draws an illustrative parallel between integrative analysis and families: The difference between having one child in a family and having two children is more than a simple doubling of the number of children; it also includes the interaction between the siblings, which may be anything but trivial (Kuckartz, 2014). Through integration, results have the potential to produce insights that would not be possible with a mere combination of data. The higher workload is “rewarded” with a higher level of “sophistication” in the results—at least this is the idea.

In terms of *purpose*, integrative data analysis strategies are particularly well suited for initiation, but also for expansion and development. If the purpose of a mixed methods study is triangulation—in the sense of researching the same topic from different perspectives in order to increase validity—analytical strategies have to be independent of each other (Caracelli and Greene, 1993; Onwuegbuzie and Combs, 2010). In this situation, integration is ill suited to the task. For triangulation, results from different data are compared and the conclusions seem more robust when all data types converge. This desired outcome implies that data have to be kept separate in order to compare the findings from different data for validity. However, although the purpose can be formulated ex ante, the realization of the purpose of mixing or integrating depends on the actual data; the purpose can emerge and change

in the process of a study. For example, although mixed analysis is intended to generate complementary results by researching different facets of the same phenomenon with different methods, the results might in practice contradict each other, precluding their integration into a bigger picture. Furthermore, when data analysis entails multiple steps or strands, different purposes can be pursued in each, depending on the respective strategy.

Generally, the starting points for integrative mixed methods analyses can be at one or more of the following four points in a project: from various data sources or elements in their more or less raw form; from data that have been preprocessed (e.g., undergone coding or indexing); during analyses, when different styles of analysis interact; or during writing when integration emerges from the writing process (Bazeley, 2018b). In the simplest form of integration, illustrative quotes from qualitative interviews complement or supplement results from statistical analyses. Although this approach can assist in communicating statistical results, “this type of integration strategy is quite limited” (Bazeley, 2012, p. 817). The highest level of integration is probably achieved when preprocessed data are integrated or when analytic styles inform and interact with each other.

Typologies and classifications

Parallel to the classification systems of mixed methods designs, there are also classifications of integrative mixed methods analysis. Commonly cited classifications include those by Creswell and Plano Clark (2018) and Caracelli and Greene (1993). Creswell and Plano Clark (2018, pp. 323–326) defined four basic integrative processes.

1. The first process involves *merging the results of analyses* of the quantitative and qualitative data sets to compare results in a narrative discussion, which means data as such are not merged, only results. Thus, integration happens more on an interpretation level than during analysis. This process assumes that analysis and interpretation are distinct steps, which may be more appropriate for quantitative research. In particular, integrative analysis is often an iterative process with analysis and interpretation going hand in hand. Thus, differentiating between data analysis and interpretation as separate steps in the research process, can be—depending on the methods employed—problematic because no data analysis is free of interpretation and ultimately all data are analyzed qualitatively “in so far as the act of analysis is an interpretation, and therefore of necessity a selective rendering, of the ‘sense’ of the available data” (Bazeley, 2018b, p. 57; see also Akremi et al., 2018; Baur and Knoblauch, 2018; Fielding and Fielding, 1986; Maxwell, 2010; Sandelowski et al., 2009).
2. The second process involves merging analyses through *data transformation*, which implies the merging of actual data. This requires one data type being transformed into another (e.g., text into numbers or vice versa).
3. The third process connects the analysis of quantitative data to the collection of qualitative data, with the latter being used to explain the former. This process represents a *sequential, explanatory model of integration*.
4. Finally, the fourth process connects the analysis of qualitative data to the collection of quantitative data, with the latter being used to build upon the former (Bazeley, 2018b, p. 62). In other words, the process is a *sequential exploratory mixed methods analysis*.

These four processes are not distinct; we notice that 1 and 2 imply strategies, whereas 3 and 4 focus on the sequence of the collection and analysis of data from different strands with no specific strategy for integration. Furthermore, one could argue that the first process is not an integrative analysis but rather a combination of interpretations. Overall, the degrees of integration and the relevance of analysis and interpretation for integration vary between these types.

Caracelli and Greene (1993) identify four integrative strategies:

1. *Data transformation*: Transformation strategies refer to the conversion of one type of data into another to allow for statistical or thematic analyses (Caracelli and Greene, 1993; Tashakkori and Teddlie, 2010), such as numerical coding or ranking of qualitative data to statistically analyze them together with quantitative data. Conversion strategies are also called “quantitizing” and “qualitizing.” Quantitizing means assigning numeric values to nonnumeric data, and qualitizing means converting quantitative data into narrative representations (Jang et al., 2008; Teddlie and Tashakkori, 2009; van Velzen, 2016). Transformation facilitates integration because different types of data can be analyzed jointly.
2. *Typology development*: The aim of developing a typology is to construct types or obtain substantive categories that allow the analysis of homogeneity within and heterogeneity between subgroupings of data. The typology is incorporated into the analysis of the respective other type of data. The typology development can be an iterative process. Results from one analysis can feed into the analysis of another form, which then feeds back into the reanalysis of the first data type. For example, dimensions identified by a factor analysis could be added to the coding of qualitative data, or typology developed with qualitative data could be included as a variable in statistical analyses and results mixed with the respective first type of data.
3. *Extreme case analysis*: Analyzing one type of data serves to identify extreme cases that can then be tested and refined with the other data type. Extreme cases are identified through analyzing one data type and further investigation of other types of data (Caracelli and Greene, 1993). The extreme cases can also guide further data collection. Thus, this approach also has the potential for iteration.
4. *Data consolidation/merging*: The joint use of both data types leads to consolidated variables or whole data sets in a qualitative or quantitative form that are comprehensively analyzed. This strategy is often considered the highest form of integration. It is well suited for initiation purposes when MMR serves the generation of new insights and perspectives.

A reviewing of this typology reveals that these four types are not necessarily distinct. Rather, they address the aim (2 and 3) and practice (1 and 4) of mixed methods analysis: Consolidation and transformation could serve for extreme case analysis or typology development. Furthermore, a practical question centers on how consolidation can be achieved. Presumably, it would contain some kind of transformation, making transformation a necessary but not sufficient step for consolidation. Furthermore, “transformation” and “merging” occur in both Creswell and Plano Clark’s and Caracelli and Greene’s typology. However, transformation was a distinct strategy for Caracelli and Greene, whereas Creswell and Plano Clark identified merging (type 4 in the Caracelli and Greene typology) as being achieved through transformation (Caracelli and Greene type 1).

Onwuegbuzie and Teddlie (2003) introduced a more process-oriented model for mixed methods analysis. They distinguished seven steps during data analysis: *data reduction*, *data display*, *data transformation*, *data correlation*, *data consolidation*, *data comparison*, and *data integration*. They extended the Caracelli and Greene typology, but again, processes are not distinct and they potentially overlap. Other approaches are more closely linked to research designs; for example, Moseholm and Fetters (2017) identified five types of data integration via merging in convergent designs. They introduced a directional dimension of merging and distinguished between *explanatory unidirectional*, *exploratory unidirectional*, *simultaneous bidirectional*, *explanatory bidirectional*, and *exploratory bidirectional*. This approach advances terminological discussions but has shortcomings regarding actual integration procedures.

Onwuegbuzie and Combs (2010) took a different approach; instead of a typology, they aimed for a conceptual framework for mixed (methods) analyses. They identified 13 aspects that can serve to delineate possibilities or decisions in mixed methods analysis. Their framework is derived from a content analysis of publications on typologies of mixed methods analyses, and it maps practices used in them. The aspects of the framework are (1) rationale/purpose for conducting mixed methods analysis; (2) philosophy underpinning the analysis; (3) number of data types that will be analyzed; (4) number of data analysis types that will be used; (5) time sequence of the mixed methods analysis; (6) level of interaction between quantitative and qualitative analyses; (7) priority of analytical components; (8) number of analytical phases; (9) link to other design components; (10) phases of the research process when all analysis decisions are made; (11) type of generalization; (12) analysis orientation; and (13) cross-over nature of analysis (Onwuegbuzie and Combs, 2010, p. 411). The advantage of this framework relative to a typology is that it is more flexible but outlines the important aspects of any mixed methods analysis.

In sum, despite a consensus on the value of integrating qualitative and quantitative approaches during data analysis, methodological reflection and practical applications remain open to further exploration. The scholarly debate lacks a common conceptual foundation, which leads to terminological confusion regarding types of designs—a confusion which, as suggested by Kelle (2007), applies to design terminologies in general. Typologies try to formalize approaches to integration and convey a sense of rigor and guidance but can also limit creative thinking. Therefore, examples of strategies for integrated mixed methods analysis seem more fruitful than overarching typologies.

I will now focus on three important integrative analysis strategies also mentioned in classifications mentioned above: data linkage, transformation, and consolidation. These three strategies entail different levels of integration. At the end of this section, I will use an example from my research that employed all three strategies (Vogl, 2019) to illustrate the implementation.

Linking data

Linking data refers to the combination of data (elements) through association, comparison, or relational analyses. Matching data for individual cases can serve comparative, additive, and/or relational (theory-building) purposes. Linking data thematically instead of by methods used to gather or analyze data is an effective means to add value to analyses and enhance integration and improve communication of results (Bazeley, 2016). Matching and comparing data within and across cases reveals the relevance of grouping variables and group patterns, and it can point to reasons for subgroup differences (Bazeley, 2018a). Group differences can be detected more easily because with linked, complementary data on a case level, “a more nuanced account of how the different data corroborate, illustrate, or elaborate each other is possible” (Bazeley, 2018b, p. 127). In addition, individual cases that diverge from the overall patterns are more easily detectable. Differences as such are still the same, but with linked data, they are easier to detect. Different sources can work together to constitute a complementary account for rich descriptions of social phenomena or to reveal differences and patterns across subgroups that might otherwise be obscured. A combined case data matrix can facilitate connections and contrasts for individual cases and across the whole sample to identify patterns but also to detect deviant cases (Bazeley, 2018b).

Data transformation

Data transformation refers to the conversion of one type of data into another to enable (a) applying a second type of analysis to the same set of data or (b) conducting a joint analysis of data from different origins. Teddlie and Tashakkori (2009) label the mixed methods design that utilizes these transformation approaches as “conversion design” (in contrast to sequential and parallel designs). The purposes of data transformation are extended understanding (Caracelli and Greene, 1993), complementarity, and initiation because consistencies and inconsistencies can be detected (Li et al., 2000, p. 126).

One approach to integrated mixed methods analyses are “cross-over analyses” or “cross-over-tracks analyses” (Li et al., 2000; Onwuegbuzie and Combs, 2010; Teddlie and Tashakkori, 2009). This is an inter-paradigmatic approach in which qualitative and quantitative data are analyzed concurrently and the analysis moves back and forth continuously. Cross-over-tracks analysis

intertwines findings from various methodological strands whereby they exchange information throughout the study. At least one type of analysis from one tradition is used to analyze data generated under the other tradition—that is, qualitative data are analyzed with quantitative strategies and vice versa.

Cross-over analysis requires some form of data transformation to make the data accessible for the analysis using a tradition other than the one under which the data were collected. The most common transformation strategy is the quantitizing of qualitative data. However, qualitzing is also possible in that quantitative data can be transformed into narratives and potentially analyzed together with qualitative data. Qualitized numeric data can offer further information or allow for cross-checking interpretations. For example, individual values on a scale can be the basis for creating narrative profiles or a typology (Bazeley, 2012; Sandelowski, 2000). Without calling it qualitzing, a sample description follows this logic. Profiles contain information about the most common characteristics or their average, and groups from within a population can be identified using cluster or factor analyses and described verbally (Teddlie and Tashakkori, 2009). In a longitudinal study, the narrative potential increases through event analyses and patterns, and sequences can guide the categorization of individuals or groups (Bazeley, 2012). A complex form of qualitzing can be found in Bourdieu's (2007) work. Based on quantitative indicators, he maps the social space and interprets this visualization qualitatively to describe social milieus. Nevertheless, qualitzing as the process of converting numerical data into data that can be analyzed qualitatively is rare, and the literature on this approach is scant (Onwuegbuzie and Leech, 2021).

Quantitizing qualitative data implies converting qualitative data into numerical data, and it is a more frequent transformation strategy. For example, an exploratory factor analysis determines thematic structures from qualitative analysis and reduces the dimensionality of qualitative data, allowing the thematic structure to be represented through a numeric coding scheme (Onwuegbuzie, 2003). In a next step, the relation and temporal adjacency of themes can be explored through multidimensional scaling and social network analysis (Christopoulos and Vogl, 2014). As another example, qualitative interview content can be transformed into numerical ratings representing evaluations of an issue. These ratings are integrated into a quantitative data set on personality measures to be analyzed together. In this way, the relations between personality traits and evaluations of an issue can be analyzed (Larner et al., 2018).

Quantitizing is a simplification that can help make large data sets more manageable, facilitate comparisons with other data sources, or allow statistical analysis (Sandelowski et al., 2009, p. 210). Thus, patterns and peculiarities that are hidden or not otherwise detectable—particularly in large data sets—can be detected by applying statistical techniques that add power and sensitivity to individual judgment (Bazeley, 2010). The most frequently used statistical procedures for quantitized data are the chi-squared test, Fisher test, Mann-Whitney U-test, bivariate correlation, or analyses of variance (Fakis et al., 2014). However, with these procedures, the complex relations inherent to qualitative data cannot be easily explained or interpreted. Multivariate analyses such as cluster analysis, multivariate regression analysis, multi-level analyses, or structural equation models would be better suited to identifying multifaceted connections in qualitative data (Fakis et al., 2014). Furthermore, nonparametric tests or multidimensional scaling and cluster or correspondence analysis (Greenacre and Blasius, 2006) pose fewer requirements on data and can facilitate exploratory analyses. Statistical techniques producing visual displays of relationships can assist in interpretive analysis—as can be seen in correspondence analysis and the mapping of social distinction (see for example Blasius and Friedrichs, 2008).

As with any data reduction process, quantitizing data is—like any categorization—a trade-off between retaining detail and managing a complex data set (Bazeley, 2018b). Some interpretive researchers condemn the use of numbers in qualitative research. Nevertheless, we frequently find quasi-quantifications such as many, often, and rarely in qualitative studies despite their limited precision and value. However, using counts of themes or codes to enhance the presentation of results or to gauge the strength of a phenomenon has a long tradition (Tashakkori and Teddlie, 2003). Ultimately, counting is a form of description and frequencies can indicate (comparative) relevance. Simple counts of themes or frequencies of codes can complement qualitative results. Quantifications cannot replace qualitative analysis—but they can be complementary or instigate new hypotheses about relationships advancing theoretical thinking.

However, numbers have a cultural and rhetorical appeal that can suggest greater generality for the conclusions than is justified. They “can be used rhetorically, to make a report appear more precise, rigorous, and scientific, without playing any real role in the logic of the study and thus misrepresenting the actual basis for the conclusions” (Maxwell, 2010, pp. 479–480). Furthermore, there is a danger of reducing evidence to the amount of evidence. In addition, compromises, judgments, and foundational assumptions in quantitizing qualitative data are typically glossed over. Sandelowski et al. (2009, p. 208) summarize the assumptions as qualitative and quantitative data constituting two kinds of data, quantitizing as a unidirectional process essentially different from qualitzing, and counting as an unambiguous process. But it is an active decision what and how to count and balancing numerical precision with narrative complexity requires compromises.

To counter these problems, researchers “must have a clear sense of why they want to quantitize at all. They must consider what the added value is of transforming qualitative into quantitative data” (Sandelowski et al., 2009, p. 219). Quantitizing should meet some criterion such as clear definition of codes and consistency in coding across the entire data set (e.g., inter-coder reliability can serve to assess consistency in coding). Furthermore, codes should be specified and illustrated with an example, particularly when a coding scheme develops in the course of a project, the data sources coded early in the project have to be reviewed for consistency, and the application of codes have to be evaluated for consistency (Bazeley, 2018b). Assuming these criteria are met, quantitizing facilitates more effective and reliable communication and analytical integrity by offsetting biased impressions (Bazeley, 2018b; Maxwell, 2010). With creative and reflexive use, quantitizing can assist in showing the complexity and multidimensionality of qualitative data (Sandelowski et al., 2009, p. 219).

Data consolidation

Data consolidation is probably the most sophisticated integration strategy. It goes beyond linking different sources of data given that it involves the creation of a new data set to support further analysis. The originally separate sources can no longer be distinguished. To achieve consolidation, qualitative and quantitative data have to be merged into a new data set. Thus, they have to take the same (or similar) format, which means some form of data transformation is required (Collingridge, 2012; Sandelowski et al., 2009; van Velzen, 2016). From this data set, it is not possible to identify the original qualitative or quantitative data; instead, genuinely new pieces of information are generated (Caracelli and Greene, 1993; Creswell and Plano Clark, 2018). Thus, qualitative, quantitative, and consolidated data can be analyzed, as well as the interaction between the three.

Consolidating data sources to create new composite variables is a generative strategy, often used to resolve puzzles raised by the data, but it can also create new questions (Bazeley, 2018b, p. 231). It often seems to be the case that consolidated data sets take a quantitative form. That is, qualitative data are transformed into numbers, and these numbers paired with the quantitative data constitute a new data set (e.g., Jang et al., 2008). However, data transformation can go both ways, quantitizing and qualitzing (Bazeley, 2018b; Vogl, 2017). Thus, a consolidated data set can also have a qualitative format.

Empirical example for integrative mixed data analysis

In a methodological research project, I studied the applicability of focus groups with children (Vogl, 2019). I conducted five focus groups with children aged 6–15 years in a rural part of southern Germany. Each focus group consisted of 8–10 participants of roughly the same age. The focus group guideline was structured by “task complexes” to facilitate comparisons. These task complexes primarily anticipated specific group processes. Some tasks were formulated to prompt the group to establish consensus (“collaboration tasks”), others to stimulate a discussion, and so on. Each focus group lasted for 45–60 min and was video recorded and transcribed in detail, including information about the addressee of communication (moderator, specific group members, the group as a whole). The analysis dealt with formal aspects, such as the progress of the conversation, group dynamics, role differentiation, and the abilities of the participating children.

Although raw data stemmed from “qualitative” data collection, a wide range of different types of information were available for analysis. Initially, I analyzed the data separately in three different strands: a qualitative, a quantitative, and a transformation strand. In the qualitative strand, utterances were analyzed regarding their type of content, for example, whether an utterance was a new aspect or a repetition or confirmation of something said before. Quantitative characteristics were word counts, number of “private” conversations in a subgroup, duration of pauses, and the number of overlapping and of incomprehensible utterances. In the transformation strand, I coded utterances with the interaction process analysis (IPA) coding scheme.

Within these strands, a group level and an individual level of analysis can be distinguished. At the group level, aggregated information was integrated to form *focus group profiles*. On the individual level, information by participant was compiled to create *participant profiles*. For the group level of analysis, I linked results from the qualitative, quantitative, and transformation strands into profiles per age group with focuses on participation and motivation and on collaboration/interaction. Original strands could still be identified in this step although they were integrated in a narrative description of the age groups. For the participant profiles, the qualitative, quantitative, and transformed information was consolidated by integrating verbal and numerical data. In essence, all results from the three strands were transformed into verbal or qualitative profiles to characterize each participant. With this consolidation into individual role profiles, age-specific types of behavior and underlying cognitive, social, and verbal skills could be defined. The results were case profiles as a new form of data, which were then compared both within and across age groups.

The *interaction analysis* in the transformation strand was the core of the study, but without additional *qualitative analysis*, participants’ role descriptions would have been too superficial. Without the additional *quantitative aspects*, age comparisons and the characterization of the course of the discussion would have been far more difficult. Furthermore, the number of words alone did not provide information on verbal or cognitive skills. Qualitative-descriptive aspects were crucial for interpreting the quantified information and giving a more detailed picture of verbal and communicative skills for children in focus group settings. Neither strand alone could have offered sufficient information to answer the research question. Qualitative, quantitative, and transformed information gave insights into partly overlapping but generally distinct aspects of the research problem. The *linked and consolidated data* offered yet another dimension of results. Linking and matching components of complementary data offered a more nuanced account of how the different data corroborate, illustrate, or elaborate on each other (Bazeley, 2018b).

The linked and consolidated data were used in a comparative analysis on the functioning of focus group discussions in different age groups and consequently facilitated meta-inferences on age-related specificities. Integrating different aspects paid tribute to the multidimensionality of the data produced in focus groups. At the same time, the extensive raw data became manageable without neglecting either the breadth or depth of the information, and systematic comparisons between age groups regarding structure and content of focus groups were facilitated. Furthermore, by merging different types of information and creating a new qualitative data set, credibility and intersubjectivity of results could be extended, thereby increasing the reach of results.

Conclusion: challenges and implications for future research

Although MMR is defined by an attempt to integrate qualitative and quantitative elements, integration is still underdeveloped and undertheorized in MMR and therefore represents a key challenge for the community. The aftermath of the paradigm wars hindered creativity in data integration. However, from a pragmatic point of view, neither philosophical nor epistemological underpinnings should guide research, but rather methods that are fit for the purpose of answering the research questions at hand. The research question and the underlying theoretical assumptions determine the processes needed for data collection and analyses. However, the link between theory and methods has to be maintained to avoid methods-centric approaches to MMR (Hesse-Biber and Johnson, 2015, p. xiii) and to resist a “mix and match syndrome” (Leininger, 1994, p. 103). Notably, MMR “should never be used because of the misguided assumptions that more is better, that it is the fashionable thing to do, or, most importantly, that qualitative research is incomplete without quantitative research (Morse, 1996)” (Sandelowski, 2000, p. 254).

MMR is not about picking methods from a toolbox with the labels qualitative and quantitative, but rather making knowledgeable choices about research designs and methods based on strengths and weaknesses (Pearce, 2012). Only a thoughtful, reflexive use of multiple methods can create added value. Yet, this should not gloss over the “spirit of adventure” (Greene, 2007) that MMR requires. Integration in MMR is often exploratory, iterative, and inherently messy. Furthermore, it requires a breadth of skills as well as imagination and the ability to envision what might be possible (Bazeley, 2006, 2012). The spirit of adventure can be a strength of MMR and promote a creative (yet reflected) use and mix of approaches—without being limited by typologies and terminologies.

Although typologies offer a framework to communicate research, MMR typologies are diverse and use various terms and terminologies. The lack of a uniform conceptual framework is one problem, while another is the limitation typologies can impose on innovation. Typologies (often) treat quantitative and qualitative analyses as unitary approaches despite the existence of many different ways of working with both numeric and nonnumeric data (Onwuegbuzie and Combs, 2010). The boundaries between these two families of methods are blurred and “now the emergence of alternative forms of data, can be considered too great for them to be seen as separate and coherent primary elements in typological models” (Bazeley, 2018b, p. 63).

The division into qualitative and quantitative data is not as straightforward as it may seem at first glance, and it is not helpful when conceptualizing mixed methods data analysis. After all, the distinction between qualitative and quantitative research is only a “straw man” (Bergman, 2008). The phenomena surrounding us are ontologically and epistemologically neutral and have both qualities and quantities. We can represent phenomena, including mental phenomena, in multiple ways using both numbers and words—or images or sounds—and indeed, in everyday life, we typically do so (Bazeley, 2018b). Thus, it becomes apparent that “qualitative and quantitative data are not so much different kinds of data as these data are experiences formed into, for example, words or numbers, respectively” (Sandelowski et al., 2009, p. 209). Quantitative and qualitative data are both created by means of the particular conceptual “lens” used by the researcher (Maxwell, 2010). Whether we use numbers, words, or images does not change the phenomenon being described or analyzed, although what we use can change how we think about the phenomenon and how we present it to others (Bazeley, 2018a, p. 336). This also means that data are always selectively constructed by researchers—not collected or generated.

For example, the data produced during interviewing or focus groups are neither qualitative nor quantitative per se. Verbal utterances would be described as qualitative data and the number of words or word share as quantitative data. However, are word counts the product of data transformation, or do they exist independently? Are we quantizing when we count words or interactions? Yes, we are, but in the same way, we would quantize verbal utterances in a survey interview when we assign a numerical value to the response. If quantizing is about converting verbal data into numerical data, then survey interviews quantize in a similar way as word counts or coding in qualitative analysis. The implication is that talking about data transformation suggests that the material underlying our research can be categorized as qualitative or quantitative. I would argue that the same material can be both. Meaning is inherent to numbers, just as numerical characteristics are inherent to verbal utterances. Data analysis—or, to be more precise, data interpretation—brings these different qualities to light. This also implies that researchers could approach the same material with different tools.

Furthermore, if data cannot be easily categorized as qualitative and quantitative, the separation of qualitative and quantitative methods is also questionable. Bergman (2008) perceives the perseverance of the labels qualitative and quantitative as being related to a considerable degree to “delineating and preserving identities and ideologies rather than to describe possibilities and limits of a rather heterogeneous group of data collection and analysis techniques” (p. 29). To conclude, the qualitative-quantitative distinction is unproductive (Miles and Huberman, 1994) and describes mental models rather than different types of data or methods (Maxwell, 2010). However, taking this thought to its logical conclusion, “If boundaries are porous, and quantitative plus qualitative is both disputed and inadequate as a distinguishing feature, is it possible to define a study as using mixed methods?” (Bazeley, 2018b, p. 7). Despite these issues, creating new terms and terminologies would add confusion and probably be similarly unsuccessful in delineating the territory (Bazeley, 2018b). Thus, we might prefer using generally recognized terms, while remaining aware of the limited value of the dichotomy in methods and data and taking account of the fractal distinction of methodologies (Knappertsbusch, 2020). Integrative thinking is not a terminology problem but mainly a practical one.

Furthermore, data integration is not only a challenge in MMR but in any study using more than one data type during the analysis—whatever data types are involved or from which source they stem. Integration can be based on the merging of qualitative and quantitative data, as well as other types of data or perspectives. Even integrating perspectives of different family members into a construction of the family as an interactional unit deals with some of these challenges (Vogl et al., 2019), as does the integration of multiple “qualitative” or “quantitative” data types in multi-methods research. Thus, strict application of terminologies limits

integration. A single, shared terminology is not absolutely necessary, but clear definitions can provide a solid conceptual framework. It is important to keep our general frameworks somewhat flexible to allow for “informed creativity” (Mertens et al., 2016, p. 3). More innovative and creative thinking in integrated data analyses and the publication of good-practice examples thereof could significantly advance the field. Of course, this innovation is not an end in itself but rather a means of promoting substantive insights in the field of education and advancing understanding and practice.

Introduction

Using software in data analysis has long been taken for granted in both quantitative and qualitative social research. Software such as SPSS, Stata, or R in the field of statistics and NVivo, MAXQDA, or ATLAS.ti in the qualitative field are widely known and used by thousands of researchers. Mixed methods research has attracted widespread interest since the turn of the 21st century. Unlike for the quantitative and the qualitative research, no special software has been developed for mixed methods analysis, but qualitative data analysis programs (so-called QDA software¹ or CAQDAS²) have integrated more and more special functions for mixed data analysis over time. Which functions these are in detail can be found in the relevant publications: Frieze (2019) for ATLAS.ti, Jackson and Bazeley (2019) for NVivo, Kuckartz and Rädiker (2019) for MAXQDA, Salmons et al. (2020) for Dedoose and Provalis (2020) for QDA Miner. On the part of statistical software, mixed methods approaches have been largely ignored; no special functions for mixed-data analysis have been developed there in the last decade.

The central point of mixed methods data analysis is the integration of the data and the results of both method strands. This is reflected in the formula “1 + 1 = 3”, which is commonly used in the mixed methods research community (Fetters and Freshwater, 2015a). The formula means that through integration, the results of a mixed methods study amount to more than the individual results of the qualitative plus the quantitative strand (Bryman, 2006; Fetters et al., 2013). The situation in mixed methods data analysis can be compared with a two-factor analysis of variance in the field of statistics. Not only the individual effects of the two factors can be identified, but furthermore—and this is even more important—the interaction of the two factors.

A widely-used and common definition of mixed methods research is that qualitative and quantitative data are involved (Creswell and Plano Clark, 2018, p. 5; Fetters and Freshwater, 2015b, p. 208), while having several data from the same research paradigm is mostly referred as multi-methods research (Fetters and Molina-Azorin, 2017). Following this definition of mixed methods, a software that allows mixed methods analysis needs to support qualitative data analysis, quantitative data analysis, and above all the combined or mixed data analysis of both types of data. In the following, we focus on this issue of combining the two types of data, because integration is a major challenge in a mixed methods research process (Ivankova, 2014). Ideally, the software allows an interactive mode of working, that means to interactively access qualitative data through quantitative data and vice versa, while working with the original data or with results tables. For example, if you are working with a qualitative interview, coding and interpreting it, you also have access to all the quantitative data about the interviewee that was collected with a survey.

¹QDA is an acronym for Qualitative Data Analysis.

²CAQDAS is an acronym for Computer-Assisted Qualitative Data Analysis Software.

Different types of integration

The emphasis on integration as one of the keys to data analysis in a mixed methods project raises several questions: What type of integration is possible in a study? What type of integration is appropriate? And in particular, what factors influence the possibilities for integration in a project? From our perspective, there are three main interrelated factors that determine the integration in a mixed methods study (Kuckartz, 2017; Kuckartz and Rädiker, 2021):

First, the design. Creswell and Plano Clark (2018) proposed a distinction between three core mixed methods designs. The “convergent design” consists of one phase in which qualitative and quantitative data are collected and analyzed, while the primary goal of this design is to compare and/or combine the results. The “explanatory sequential design” consists of two phases. After collecting and analyzing quantitative data, the collection and analysis of qualitative data follows. And the “exploratory sequential design” starts with a qualitative phase which is followed by a quantitative phase. There are several other suggestions for naming and grouping mixed methods designs (e.g., Plano Clark and Ivankova, 2016; Tashakkori et al., 2021; Tashakkori and Teddlie, 1998), but only by focusing on “convergent/parallel” vs “sequential” as one of the main distinguishing criteria, it is obvious that integration in these design types has to follow different rules. In sequential designs, primary integration usually takes place *after* one of the strands has been analyzed to inform and shape the second phase. In convergent designs, integration can start during analysis phase, while in any mixed methods design, results of both strands can be combined and compared at the end.

Second, the purpose and the justification for selecting a mixed methods approach. If the purpose is greater validity and triangulation to evaluate the convergence of the results of the qualitative and the quantitative strand (Bryman, 2006; Greene et al., 1989), it might be misleading to start the integration during the analysis phase or use the results from one strand for data collection in the other. Instead, integration can usually begin only after both strands have been completed, thus the purpose determines the design and thereby the point in time and possible type of integration. But if the purpose is completeness and illustration (Bryman, 2006), it might be crucial to start the integration during data collection and combine data for individuals during analysis. This leads directly to the third determinant.

Third, the samples. Creating a table with qualitative and quantitative information for each case in a single row, as discussed in detail in Schoonenboom and Johnson (2021) and illustrated in many studies like the one of Leal et al. (2018), requires a sample that allows the matching of qualitative data and quantitative data for each person. If I have two samples with different people or if I collect qualitative and quantitative data from the same sample of people but cannot link both types of data due to privacy issues, the scope of integration possibilities is limited.

With these determinants in mind, we have developed twelve integration strategies which can be divided into four different types:

1. *Results-based integration:* The researchers combine, compare, and relate the results of the qualitative strand and the quantitative strand. Therefore, the analysis of both kinds of data has already been completed, at least partially, before the integration step.
2. *Data-based integration:* The researchers work with both kinds of data during the analysis phase. Data-based integration requires a “nested” or an “identical sample” (Onwuegbuzie and Collins, 2007), i.e., there are cases for whom qualitative and quantitative data have been collected. Furthermore, it must be possible to clearly assign the qualitative and quantitative data to the individual cases.
3. *Transformation-based integration* is a sub-part of data-based integration: qualitative data is transformed into quantitative data and, less common, quantitative data is transformed into qualitative data.
4. *Sequential integration* is used if the results of one strand inform the development of data collection instruments, the sampling strategy, or other aspects of the subsequent strand.

Figs. 1 and 2 locate these four types of integration in the course of mixed methods projects. Although types of integration can be combined within a project, usually, not all types of integration are carried out in the same mixed methods study. For example, data-based integration is typically used in convergent designs and is therefore rarely combined with sequence-oriented integration.

For all types of integration strategies, so-called “joint displays” play an important role. In a joint display, qualitative and quantitative data and/or results are arrayed together, and typically, a joint display consists of a table, conceptual graphic, or geographic map, but it also can follow a free-form (Fetters and Guetterman, 2021; Guetterman et al., 2015a,b, 2020). Joint displays serve as a tool for analysis and presentation of findings as well as for verifying and creating hypotheses. From our point of view, it is important that a software for mixed methods data analysis supports the creation of joint displays.

In the following sections, for each of the four types of integration, we will present appropriate strategies for combining qualitative and quantitative data and results and for creating joint displays with computer software. Each description of a strategy follows a defined structure, starting with a short description, followed by its application with computer software and additional notes. When we refer to software in the following, we mean QDA software or CAQDAS, because these are the most advanced in terms of mixed methods functionality. If we refer to other types of software, this is explicitly mentioned.

Using software for results-based integration

Results-based integration strategies can be conducted in any mixed methods study, because they rely on the findings from the qualitative and the quantitative strand. The typical goal of results-based strategies is to compare the qualitative and quantitative findings on specific research questions, topics, and themes. Of course, such a comparison only makes sense if both strands analyze the same

Fig. 1 Different types of integration in a convergent mixed methods design.

aspects of a phenomenon, thus, results-based integration strategies are common in a convergent design, particularly in those pursuing the purpose of triangulation. Results-based integration requires that the results of the qualitative and quantitative strand are available as written sub-reports or at least as compilations of partial results, graphs, and statistical tables (Kuckartz and Rädiker, 2019, p. 175). We describe two strategies for comparing and integrating the results using software: the first strategy connects qualitative and quantitative results by using hyperlinks and the second juxtaposes the results side-by-side in a table.

Strategy 1: Connecting results with hyperlinks

Description: Thematically related portions of the study results from both reports are hyperlinked so that when writing the final report, one can quickly find, relate, and summarize related results.

Implementation with software: To link related results of both strands, one can follow these steps:

1. Import both reports into the software and open them. If a second screen is available, one report should be placed there. Alternatively, both reports can be displayed in “tabs” as known from internet browsers or placed next to each other on a wide screen.
2. Start with reading one of the reports and search for relevant results and findings, for example, on willingness to pay fair prices on sustainable products (topic 1) and on actual behavior regarding sustainable consumption (topic 2). Using text search with relevant search items can help identifying sections. Highlight an identified section and mark it as the start of an internal link.
3. Go to the other report to identify and highlight a part related to the previously selected section; again, text search might be helpful. Set the target of the internal link to connect both sections. Now, if you click on the start or the target, the corresponding section in the other report will be focused and presented. You can add memos to the linked parts to record the addressed research question or topic.
4. When writing the integrative final report, use the memos for fast access to the thematically important links.

Notes: This is a universal type of integration that can be used whenever the results of a quantitative and a qualitative strand are to be compared. This integration strategy is primarily used in studies that work with different samples in the qualitative and quantitative strand, in other words, one does not have both types of data for each person. However, this strategy can also serve as a complement

Fig. 2 Different types of integration in an exploratory sequential design.

for data-based integration strategies. Setting links during the analysis process is easy to accomplish, and when writing the research report later, it is possible to jump from one result to another very quickly.

Strategy 2: Side-by-side display of results

Description: The results of the qualitative and quantitative strand are juxtaposed and compared in a table. The table is structured by research questions or topics of interest (Table 1).

Implementation with software: Creating a side-by-side display with software is straight-forward because it relies on commonly used thematic coding techniques.

1. Create codes that reflect the research question and that can serve as the structure of rows, such as “Willingness to buy fair trade products” and “Actual behavior” in Table 1.
2. Work through the qualitative and quantitative sub-reports and apply the codes to relevant parts that contain substantial findings for the topic.
3. For both sub-reports, retrieve the coded segments for a topic and place the compiled results in the related cells of the side-by-side display. The cells of the table can contain the original texts, diagrams, and statistical tables from the sub-reports. This is no problem in the software where one can scroll even very large tables but, for integrating a side-by-side display into a report, the results are presented usually in a condensed and summarized form. The summaries can be written in the software and integrated in the table instead of the original sections.

Notes: If the software has no built-in function for creating side-by-side displays, you will need Word or another text-processing application to create the table. Creating a side-by-side display in the software can be an intermediate step for creating a more condensed form of this joint display in the final report. Often, an additional column containing the discrepancies and confirmations between both strands is included in the final joint display.

Using software for data-based integration

In data-based integration, qualitative and quantitative data are integrated during the data analysis phase, thus it is not a requirement that the results of both strands have been written down in a report. Integration and mixed analysis are carried out directly with the data and partial results during the data analysis phase. Data-based integration can be performed with all cases of a study for which both qualitative and quantitative data are available. The data must be clearly assignable to each case or group of cases: If qualitative interviews and quantitative questionnaires were used in a mixed methods study, it must be possible to assign the questionnaire data to each interviewee or at least a group of interviewees. For this reason, data-based integration is typically used in parallel designs, seldomly in sequential designs.

When it comes to data-based integration, particularly QDA software offering mixed methods features shows its full strength and actually none of the strategies no. 3 to no. 8 can be accomplished in a reasonable way without the use of QDA software. Most of the presented strategies rely on having the qualitative and quantitative data for each case included in the same project file to be able to use one of them to access cases (strategy no. 3), group cases (strategies no. 4, 5, 6), or present both kinds of data for each case in a table or diagram (strategies no. 7 and 8). Typically, for each qualitative case, a set of quantitative data is stored as so-called variables or attributes in the software.

Strategy 3: Qualitative exploration of quantitative extreme cases

Description: The quantitative data are used to identify “divergent and extreme cases” (Bazeley, 2018, p. 272) in order to further analyze their qualitative data (Creswell and Plano Clark, 2018, pp. 235–236). The quantitative data is the starting point for accessing and selecting qualitative cases for further investigation and for answering the questions *why are* and *what makes* these cases so special.

Implementation with software: This strategy consists of three steps, starting with (visual) analysis of quantitative data to identify special cases, storing of these cases, and their subsequent qualitative analysis.

1. Look for extreme cases by sorting variables by their values in the quantitative data table or by using charts, such as boxplots and scatterplots. Fig. 3 shows a scatterplot, a sorted column of one variable, and a boxplot with the extreme cases highlighted in each

Table 1 Schematic example of a side-by-side display.

	Qualitative strand	Quantitative strand
Willingness to buy fair trade products	Results, as (summarized) text, diagrams	Results, as (summarized) text, charts, statistical tables
Actual behavior	Results, as (summarized) text, diagrams	Results, as (summarized) text, charts, statistical tables

chart. In the scatterplot, people that have a very high value on one or both of the variables “environmental awareness” and “environmental behavior” are highlighted (please note that the graphics are not taken from a real study but created for illustration).

2. Store the identified cases or mark them as special cases, by adding a memo, changing their document color, or adding another variable. If groups of special cases are identified, they can be stored in a set of documents for joint exploration.
3. Analyze the identified cases by working through their qualitative data. If their data has already been coded, the code frequencies and code patterns can be included in the analysis.

Notes: It is also possible to use this strategy in the opposite direction. Qualitative extreme cases are identified, for example, by searching for interviews with a noticeable large number of coded segments regarding the purchase of sustainable products or with people who reject these products completely (Rädiker and Kuckartz, 2020, pp. 98–99). Subsequently, their quantitative data are analyzed and compared with those of the other study participants.

Strategy 4: Qualitative themes by quantitative groups

Description: In a tabular joint display, the qualitative data are compared by groups formed by quantitative data. The quantitative groups build the columns, the themes form the rows, and the cells contain the qualitative data (Table 2). If interviews have been conducted for the qualitative part, the cells can contain the original responses of the interviewees or a summary of the content written by the researchers.

Implementation with software: This strategy requires that the qualitative data have already been coded.

1. Select relevant codes that you want to compare by groups.
2. Select a quantitative variable as the differentiating criterion for grouping, e.g., a socio-demographic variable such as age groups or a test score of a person.
3. For each cell, retrieve the coded segments of the cases sharing the same variable value of their group and copy the segments into the table cells of the *qualitative themes by quantitative groups* joint display or use a built-in feature to create it automatically. If the content of the cells is very large, it might be helpful to summarize it before including it in the table.

Fig. 3 Visually identifying divergent cases in a boxplot, a sorted list of variables values, or a scatterplot

Table 2 Qualitative themes by quantitative groups (joint display).

Qualitative themes	Awareness score: low	Awareness score: medium	Awareness score: high
Willingness to pay fair prices	Segments coded with “willingness ...” of persons with low score	Segments coded with “willingness ...” of persons with medium score	Segments coded with “willingness ...” of persons with high score
Actual behavior	Segments coded with “actual behavior” of persons with low score	Segments coded with “actual behavior” of persons with medium score	Segments coded with “actual behavior” of persons with high score

Notes: Similar to the side-by-side display of results, software allows one to work with larger tables during analysis, because they can be scrolled vertically and horizontally, but for printing and presentation it is necessary to create a condensed form of the table. When comparing several groups but only two or three themes, rows and columns can be switched to create more print-friendly tables with smaller width.

Strategy 5: Frequency of qualitative themes by quantitative groups

Description: In a tabular joint display, the qualitative data in form of code frequencies are compared by groups formed by quantitative data. This joint display is similar to the qualitative themes by quantitative groups in [Table 2](#), but the cells contain the frequencies of the coded themes in place of the texts or summaries.

Implementation with software: This strategy requires that the qualitative data have already been coded.

1. Select relevant codes that you want to compare by groups.
2. Select a quantitative variable as the differentiating criterion for grouping, e.g., a socio-demographic variable such as age groups or a scale or test value of a person.
3. Identify the number of coded segments or cases for which a theme has been coded and record this number in the cell of the results table or use a built-in feature to create it automatically. If the number of segments or cases is high enough, it might be helpful to use percentages instead of absolute frequencies. Thus, statements can be made such as “25% of the interviewees with a low awareness score expressed a strong willingness to pay fair prices for sustainable furniture.”

Notes: Quantification of qualitative data is not unproblematic and should be carried out after ensuring that it makes sense to analyze the code frequencies in this way (see also strategy 9 “quantitizing” below). Instead of working with the number of coded segments per theme, it is often a better and more reliable approach to work with the number of cases for which a theme has been coded, because the code frequency is influenced by many factors such as coding strategies and different data structures.

Strategy 6: Statistics by qualitative groups or types

Description: In a tabular joint display, quantitative statistics are compared for groups or types formed by the qualitative data. The groups or types are used as columns, while quantitative variables build the rows. For categorical variables such as the “Number of children”, the number of cases and a percentage value are presented in the cells, and for variables with interval scale such as “Awareness score”, the average mean and the standard deviation are shown ([Table 3](#)).

Implementation with software: This strategy requires that the qualitative data have already been analyzed and groups of cases have been identified or types have been built.

1. Select a code containing sub-codes that reflect the groups or types to be compared and convert it into a “qualitative” categorical variable to record the belonging to a group or type for each case.
2. Select the quantitative variables for the rows. Naturally, these should be variables for which one expects differences between the qualitative groups or types.
3. Select all cases of a group or type by using the grouping “qualitative” variable and calculate mean, standard deviation, number of cases and the respective percentage value for the selected row variables. Repeat this for all groups and types—or use the in-built feature of the software to create the results table in one step.

Notes: Highlighting the lowest and highest value per row helps to interpret the resulting joint table by allowing patterns to be identified, especially if a qualitative group holds most or all lowest or highest values.

Table 3 Statistics by qualitative groups or types (joint display).

Qualitative themes	Environmental ignoramuses	Environmental greenies	Environmental pragmatists
Awareness score	Mean (standard dev.)	Mean (standard dev.)	Mean (standard dev.)
Number of children	Number (%)	Number (%)	Number (%)

Strategy 7: Case comparison table with mixed data

Description: Data and analysis results from qualitative and quantitative strands are compiled in a tabular overview organized by cases. Each row of the table contains information about a case unit of the mixed methods study, e.g., a person, an institution, a family, or an organization. In the columns, coded segments or thematic summaries as well as variable values, scale values, or values calculated by statistical analyses (e.g., factor scores, cluster membership etc.) are displayed. Case comparison tables are commonly used to present research findings in publications or on conference posters (Schoonenboom and Johnson, 2021). They can also be used in other phases of a mixed methods project, such as to discover differences between cases or to find similarities and group cases accordingly (Bazeley, 2018).

The case comparison table in Table 4 was developed as part of an evaluation of a university statistics course (Kuckartz et al., 2008). It contains the data of four case units, namely the interviewees “I1”, “I2”, “I3”, and “I4”. The columns show four qualitative categories and the respective thematic summaries are listed for each case unit. The last two columns contain the individual values of two selected variables from the quantitative strand and one of these is used for sorting the table.

Implementation with software: Case comparison tables require that the qualitative data have been coded beforehand. It is also highly recommended to create thematic summaries per case unit for important categories. Summaries will make the table much more readable than full text segments. To create a case comparison table, proceed as follows:

1. Select the cases to be included in the table. The cases form the rows of the table. Usually, the case identifiers (and some demographic data) are displayed in the first column. It is also possible to group case units and then compare the groups in the table.
2. Select the codes whose coded segments or thematic summaries should be displayed in the columns.
3. Select the variables whose values should also be displayed in columns of the case comparison table.
4. Arrange the columns of the table in a meaningful order. Experiment with different ways to sort the table according to the contents of the columns.

Notes: Usually, the construction of a case comparison table goes through several stages (Schoonenboom and Johnson, 2021): additional codes or variables are added or removed from the table. Columns are sorted to list similar cases as close to each other as possible, and thematic integrative summaries are written or existing summaries are modified.

When constructing case comparison tables information overload should be avoided. This means that careful consideration should be given to whether the inclusion of a category or a variable really adds analytical value. If a study includes many cases, a reasonable selection should be made, or groups should be formed. Case overviews that extend over several pages should be avoided.

Case comparison tables have a twofold function; on the one hand they are an important tool of exploration and help to discover relationships and patterns in the data. Secondly, they can also serve as a means of presenting similarities and differences of cases. They can be used as a joint display in research reports and presentations to illustrate the results of a mixed methods study.

Strategy 8: Case maps with mixed data

Description: Visualizations such as the case map in Fig. 4 can show important characteristics of a case, e.g., of an interviewed person. In such a joint display, both qualitative and quantitative data are integrated.

Implementation with software: In principle, case maps may be created with any graphics software as well as with PowerPoint and similar presentation software. However, there are many advantages to using QDA software to create case maps, because this maintains a direct link to the original data. If one clicks on the corresponding symbols in the case map shown in Fig. 4, the underlying text passages are called up immediately.

Table 4 Case comparison table for four cases; standardized quantitative data marked with [x]; sorted by “Math grade at school”.

Literature usage	Study group	Expected exam result	Main attitude	Participation tutorial [x]	Math grade at school [x]
I3 No answer, probably no additional literature usage	Yes, for exam preparation	Pass! everything better is good	Fear pass!	Rarely	B
I2 Textbook completely worked through	Little, only once and again for exam preparation	No A, more a C	Interest ambitions	Very often	C+
I4 Textbook passed around in study group	Yes, during the whole semester	Pass! C would be nice	Interest	Rarely	C
I1 Only reader no further literature	No, only asking a friend during exam preparation	Pass!	Interest pass!	At least every 2nd week	D+

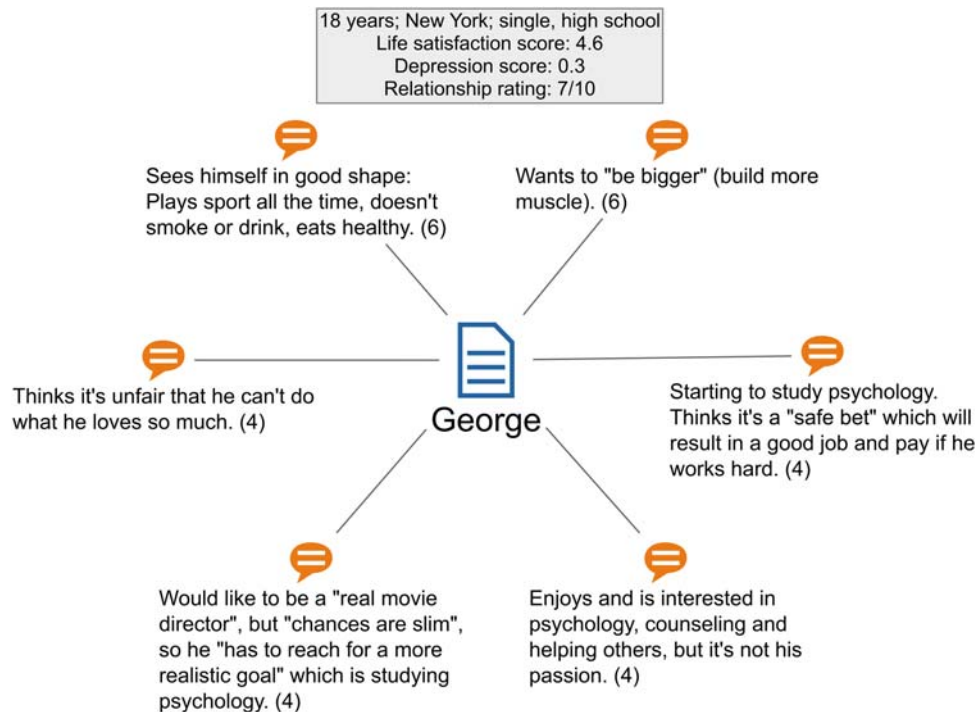

Fig. 4 Case map for the interviewee George

Notes: Case maps open up a variety of possibilities for creative social researchers; for example, photographs, images, and film clips can be incorporated and played when presenting research findings at conferences.

Using software for transformation-based integration

These types of integration strategy are based on the idea of performing the final data analysis with only one type of data, i.e., only as a qualitative analysis or only as a statistical analysis of quantitative data. For this purpose, a harmonization of the data type must take place, either a transformation of qualitative data into quantitative data ("quantitizing") or a transformation of quantitative data into qualitative data ("qualitizing"). On the one hand, both types of transformations are necessarily associated with information losses, but on the other hand, they also offer new opportunities to use approved methods of data analysis, e.g., cluster analysis, correlation, or regression analysis in the case of quantitizing.

Strategy 9: Quantitizing—transformation of qualitative into quantitative data

Description: The results of the qualitative component are transformed into quantitative variables using a methodologically controlled, usually automatic, transformation process. Through this "quantitizing", the results of both components are then available in quantitative form and the interrelationships can be examined using statistical methods.

Implementation with software: The transformation of the qualitative data can be done in several ways. A simple method is to record the frequency of application of a code per case as the value of a variable with a corresponding name. This method does not need to be described further, the software only needs to be able to perform the transformation automatically and store the data. More sophisticated is the transformation of a code with subcodes into a categorical variable. This strategy consists of three steps, which are described here in relation to a single category and its transformation:

1. *Code* qualitative data in such a way that a category is defined, and the subcategories capture the dimensions of this category. For example, the text passages of an interview that deal with the personal engagement of the research participants will be coded with the subcategories "low", "medium", "high" and "not mentioned".
2. These qualitative data are now *transformed* to create a quantitative variable "personal engagement" and the most frequently coded subcategory for each research participant is stored as a variable value.
3. Now *analyze* the data from the qualitative component, which was formed by means of transformation, for its interrelationships with the quantitative variables with the help of statistical methods. The condensed information obtained by the transformation (e.g., about the personal commitment per document) can be used for further analyses, e.g., to group research participants, to contrast them, or, for example, to compare the low-committed and the highly committed with each other.

Notes: Quantitizing strategies have been proposed for some time as a possible way of integrative analysis, e.g., with the aim of calculating relationships between qualitative and quantitative variables (Onwuegbuzie and Teddlie, 2003). The applicable statistical methods depend on whether the newly created variables fulfill the requirements of those methods. For example, depending on the appropriate level of measurement, parametric statistics or non-parametric statistics can be used. There are numerous examples in the literature of types of complex statistical analysis with quantified qualitative data. For example, van Haneghan (2021) reports about the usage of factor analysis, Cox et al. (2021) applied multiple linear regression, and Newman and Constantinides (2021) used structural equation modeling. Many more examples from research projects can be found in “The Routledge Reviewer’s Guide to Mixed Methods Analysis” edited by Onwuegbuzie and Johnson (2021).

Strategy 10: Qualitizing—transformation of quantitative into qualitative data

Description: Data from the quantitative study are transformed into qualitative data, usually narratives (Onwuegbuzie and Teddlie, 2003). In the simple case, the classification of a person on a scale or an index or the values for individual variables are expressed in words. For example, the information “132” of a variable “IQ” is transformed into the words “very intelligent”. Complex forms of qualitizing can create “comparative narrative profiles” based on complex statistical analyses such as cluster analysis or factor analysis (Onwuegbuzie and Leech, 2021).

Implementation with software: For qualitizing, there are no algorithmic procedures available as there are for quantitizing. This strategy consists of three steps, which are described here in relation to a single category and its transformation:

1. *Select* the variables, scales, or indices to be transformed. Under certain circumstances, it may be useful to first examine the interrelationships of several variables, e.g., the mutual correlation or, in the case of categorical variables, the correlations via cross-tabulation. Also, analysis procedures such as cluster analysis, factor analysis, or discriminant analysis can be performed first. Corresponding statistical calculations can be performed using statistical software or QDA software that supports these calculations.
2. *Transform* the numbers into words and sentences. For metric variables, it may be helpful to calculate mean and distribution measures. For ordinally scaled variables, calculate the median and quartiles or percentiles. This makes it easier to estimate the values of the persons or cases studied in relation to their position within the population of cases included in the study. The words and sentences formulated should remain close to the data and the wording should be respectful. For example, one should avoid referring to people with non-climate-responsive behaviors as “irresponsible citizens” or people who drive SUVs as “reckless horsepower fetishists”. The new qualitative data generated by the transformation should ideally be stored in the QDA software as a document memo for a case. It is also conceivable to insert these data as new texts in the project file and to code text passages with codes of the code system.
3. Now analyze in an integrated way by combining the data generated by qualitizing with the results of the qualitative component in a coherent text. This can be done by writing integrative memos. If the new data have been inserted and coded as their own text in the project file, joint displays can be created, which allow direct comparison of the results of the qualitative and quantitative strand in convergent designs.

Notes: Although the strategy of qualitizing is not chosen as often as the strategy of quantitizing in mixed methods research (Onwuegbuzie and Leech, 2021), it is by no means only applicable in special cases. Meanwhile, approaches of qualitizing are more frequently described (e.g., Vogl, 2019; Yousefi Nooraie et al., 2020) and also realized in mixed methods research (e.g., Headley and Plano Clark, 2020; Waller et al., 2021). This strategy appears to be particularly suitable when the qualitative strand is assigned greater relevance in the corresponding design of the mixed methods study. Qualitizing is also a promising option if publication in a qualitative research journal is intended.

Using software for sequential integration

At first glance, it looks as though researchers do not have to worry about integrating qualitative and quantitative strands when working with sequential mixed methods designs. While meta-studies on mixed methods research have often diagnosed the lack of integration of strands in convergent designs, a sequential design is not even thinkable without integration: study component A, conducted first, is by definition the precondition for study component B, which builds on its results. Integration is quasi-inherent to sequential designs, but the linking of the two components should be methodologically controlled and not just intuitive, and QDA software can play an important role in this integration process.

Strategy 11: Developing a quantitative strand based on qualitative results (exploratory sequential design)

Description: Designs in which a qualitative strand is conducted in the first step are also referred to as exploratory designs. The motive for such designs can be, for example, the need to extend or generalize the findings of the qualitative strand. The construction of a questionnaire for a subsequent survey is done in very close relation to the qualitative results. The source for each question and the reasons for asking this question with these answer specifications are recorded, so that the empirical foundation of the questions in the questionnaire is transparent at any time.

Table 5 Template for the development of a questionnaire in exploratory design.

<i>Source</i>	<i>Questionnaire</i>
Theme A: Findings of the qualitative strand	Question 1
Theme B: Findings of the qualitative strand	Question 2a to 2f
Quality of life scale according to WHO	Question 3a to 3f
Subcategories of category C of the qualitative strand	Question 4a to 4f
Demographic data	Question 5 to 9

Implementation with software: A direct development of a more or less immediately useable online questionnaire with the help of QDA software is not possible so far. No QDA software offers this function and probably will not do so in the future because, with software like Lime Survey, Qualtrics, or SurveyMonkey, highly specialized tools for the construction of online surveys are already available. However, QDA software can provide important support for the development of the quantitative strand, for example by recording on which results of the qualitative strand the questions of the newly constructed questionnaire are based or what the background for the construction of the questions is.

We recommend creating a correspondence table similar to **Table 5** for the design of the questionnaire; such a table can be created as a table document in the QDA software. The questionnaire to be constructed is gradually developed in the second column, while the source for each question is designated in the first column. The entries can be linked to the corresponding data or coded using the code system.

Of course, in a study with exploratory sequential design, not all questions included in the questionnaire have to be directly related to the results of the qualitative strand. It is standard practice to ask for demographic information such as age, gender, and place of residence. It may also be useful to collect supplementary quantitative information, for example, to include tests or well-established scales in the questionnaire.

Notes: Examples of using joint displays in exploratory designs can be found in [Ho et al. \(2021\)](#), [Munce et al. \(2021\)](#), and [Shim et al. \(2021\)](#).

Strategy 12: Developing a qualitative strand based on quantitative results (explanatory sequential design)

Description: Mixed methods designs, in which a quantitative strand is conducted in the first step, are also called explanatory designs. The motive for such designs, in which the qualitative strand builds on the quantitative strand, can be the desire to deepen the results of a survey or to clarify analysis results that cannot be explained with previous knowledge.

Implementation with software: How and in what way QDA software can support the design of a qualitative in-depth strand depends to a considerable degree on the planned method of qualitative data collection and the degree of openness.

If the qualitative strand is planned in a very open way, for example to better understand surprising results, one will only note very general keywords for narrative interviews or focus groups. In the software, memos should be used to record exactly why these findings should be explored in more depth. Such planning memos can be linked to the original data of the corresponding text passages of the quantitative research report.

If the subsequent qualitative strand is planned with a more structured approach, a detailed guideline for interviews or focus groups should be developed, the individual points of which are each linked to the corresponding results of the quantitative strand. Technically, this can be realized by creating the interview guide as a new document in the QDA software and linking each of the individual points to the results of the quantitative strand.

In an explanatory design, the integration does not only take place during the planning of the subsequent qualitative strand, but there is a second point of integration. After completion of the qualitative strand, the results of both project phases should be presented in a joint display. In this display, an overview should be given of which of the results of the quantitative strand can be better explained by the qualitative strand and which are still open. The joint display (**Table 6**) is similar to strategy 2 (side-by-side display of results).

Notes: Many suggestions for using joint displays in explanatory designs can be found in the literature, e.g., [Alexander et al. \(2021\)](#), [Ivankova et al. \(2006\)](#), and [Waller et al. \(2021\)](#).

Table 6 Template for a joint display in an explanatory mixed methods study.

<i>Quantitative strand</i>	<i>Findings of the qualitative strand</i>
Results that require explanation (based on the results of statistical analysis, e.g., correlations, regression analysis, factor analysis etc.)	Results clarified by the outcome of the qualitative strand. Results that could not be clarified even by the results of the qualitative strand.

Overview of strategies for integration and required software features

Most of the presented twelve strategies cannot be accomplished in a reasonable way without QDA software. At the time of writing this chapter, several competing software products are offered. Since QDA software, as well as the corresponding market, changes very quickly it does not seem reasonable to create a software comparison table, which necessarily becomes outdated quickly. The requirements that suitable software for mixed methods analysis must meet also depend to a large extent on the parameters of the specific project, for example, the types of data that have been collected, the size of the samples, the type of analysis method, etc. It makes a big difference if video data has been collected, because the software must of course be able to analyze it. It also matters if several types of data are combined, for example, if focus groups and narrative interviews were conducted, and documents are to be analyzed at the same time. Very important is what types of data can be handled (videos, paintings, photographs, Twitter data, YouTube comments, ...) and which file formats can be imported (docx, xlsx, pdf, png, mp3, mp4). Before starting the analysis, it is strongly recommended to check carefully whether the QDA software offers the required functionality. Some features should be met as basic requirements in any case:

- For all kinds of data-based integration, the QDA software needs to be able to import qualitative and quantitative data and connect them on a case level.
- QDA Software should be able to handle multiple qualitative data sources with different samples, such as focus groups, interviews, documents.
- Advanced features of searching and automatic coding should be provided.
- Options for linking different data should be available.
- In general, results tables should be interactive so that it is easy to jump from qualitative to quantitative data (and vice versa).
- At least a minimum of descriptive statistics functions should be available, as well as the ability to aggregate variables and build scales.
- Different types of joint displays for integrative analyses should be offered.

In [Table 7](#), all twelve integration strategies are listed once again. The second column indicates for each strategy which functionality the software must provide.

Most of the 12 strategies presented in this chapter and the corresponding joint displays are created in several cycles, i.e., experimentation is carried out until an optimal result is achieved. [Fetters and Guetterman \(2021\)](#), for example, have described this very impressively for the emergence of a Joint Display “Stakeholder perspectives on ethical advantages and disadvantages to adaptive clinical trials from the patients” that has been developed in seven iterations. To be able to realize such cyclical processes in a reasonable time, the software must be as interactive and flexible as possible.

Summary and conclusions

The community of mixed methods researchers agrees that integration is the crucial point of mixed methods approaches. Regardless of whether basic designs or fully integrated designs are involved, integration is generally unthinkable today without using QDA software. Software is needed that ideally allows the analysis of both qualitative and quantitative data. Only with such software can joint displays be created, in which qualitative and quantitative results are integrated. Of course, one can create such displays with Word, Excel, and PowerPoint, but the main advantage of QDA software is the interactivity of the joint displays ([Rädiker, 2018](#)).

Nevertheless, you should keep in mind that QDA software (CAQDAS) was originally created for qualitative data analysis. Special functions for mixed methods analysis were only developed over time as add-ons. This still results in some limitations at present. For example, the range of statistical analyses is not yet fully covered and there are no templates for established mixed methods designs. The guidance for typical analysis procedures in mixed methods research is therefore not yet optimal but is constantly being improved.

There are currently several QDA software packages on the market that fulfill the requirements listed in [Overview of strategies for integration and required software features](#) section to varying degrees. Since QDA software is constantly being developed further, one should check the current status of the packages and test available trial versions before planning a mixed methods analysis.

Ideally, software for mixed methods data analysis should have the ability to analyze both qualitative and quantitative data. Since many projects nowadays collect more than one type of data at a time (e.g., survey and qualitative interviews), the software should also be able to analyze many types of data simultaneously, such as surveys, qualitative interviews, focus groups, documents, videos. In addition, it must offer a wide range of possibilities for integrating both streams, and in this field joint displays are particularly important. Integration is a major challenge of mixed methods research and software is essential to meet this challenge.

Table 7 Twelve strategies of integration and necessary features in QDA software.

<i>Integration strategy</i>		<i>Software facilitates to ...</i>
Results-based integration		
1	Connecting results with hyperlinks	• Create internal links between parts of data and add notes or memos to them • Optional: compile links in a list for easy access
2	Side-by-side display of results	• Create a table with coded segments from qualitative and quantitative sub-report • Optional: write summaries of coded segments
Data-based integration		
3	Qualitative exploration of quantitative extreme cases	• Store quantitative data in variables for each case • Create charts for quantitative data, such as boxplots, scatterplots, histograms
4	Qualitative themes by quantitative groups	• Sort, select, and group cases by their variable values • Store quantitative data in variables for each case • Retrieve coded segments per sub-group that have been created by variable values and display them in a table
5	Frequency of qualitative themes by quantitative groups	• Optional: write summaries of coded segments • Store quantitative data in variables for each case • Calculate frequencies and percentages of cases or coded segments per sub-group that have been created by variable values and display them in a table
6	Statistics by qualitative groups/types	• Store quantitative data in variables for each case • Calculate mean and standard deviation for sub-groups and determine numbers of cases in a sub-group where a code has been applied; display these results in a table
7	Case comparison table with mixed data	• Store quantitative data in variables for each case • Create (interactive) tables containing quantitative variable values and qualitative summaries for each case
8	Case map with mixed data	• Store quantitative data in variables for each case • Create concept maps containing qualitative and quantitative elements that are linked to the original data
Transformation-based integration		
9	Quantitizing: transformation of qualitative into quantitative data	• Store quantitative data in variables for each case and to transform code frequencies into variable values
10	Qualitizing: transformation of quantitative into qualitative data	• Transform coded subcodes into categorical variables • Store quantitative data in variables for each case and compute statistical analysis like building reliable scales • Write integrative memos containing the results
Sequential integration		
11	Developing a quantitative strand based on qualitative results	• Create new document (questionnaire) • Link data and results to specific questions in the questionnaire • Create displays for the joint presentation of the findings
12	Developing a qualitative strand based on quantitative results	• Create new document (interview guide) • Link data and results to the interview guide • Create displays for the joint presentation of the findings

High-quality research is characterized as justified in its selected approaches and procedurally transparent leading to outcomes that are viewed as viable, and finding that are viewed as applicable to stakeholders. Conceptually it is multidimensional construct comprising the transparency of the methodology, application of standards associated with self-selected intellectual communities, and construction of a validity design occurring at various junctures within the study (Collins, 2015). A strand, as a term defining the approaches (quantitative qualitative) of the study, was coined by Tashakkori et al. (2020). A strand comprises the following three stages of a study: (a) conceptualization stage, whereby the researcher forms the basis of the study, such as defining the purpose and the research questions; (b) experiential stage whereby the researcher makes the methodological and analytical decisions relative to implementing the study; and (c) the inferential stage, at which point the researcher forms conclusions per strand and integrates these conclusions leading to meta-inferences concerning the phenomena of interest. A meta-inference denotes an inference formulated based on the integration of inferences derived from the results obtained from qualitative and quantitative strands within a study (Tashakkori et al., 2020).

In this chapter, strand is the preferred term referring to the approaches implemented in an IMMR design. A critical aspect of high-quality research is design and implementation of quality criteria that will address concomitantly the rationale and purpose for integration, the research question addressed in the study, and the level of integration viable given the study’s design. Also in this chapter integration is the preferred term for mixing. The goal of this chapter is to prompt the design of high-quality research by discussing quality criteria within the context of integrative mixed methods research (IMMR), hereafter referred to as IMMR. The first purpose is to conceptualize integration as an evolving concept and to illustrate this evolution by presenting selective scholarly interpretations of integration within IMMR literature. The second purpose is to discuss the concept of inference as it relates to design decisions. The third purpose is to present selective approaches to designing quality criteria obtained from the published literature. I conclude this chapter with an outline of examples of empirical perspectives obtained from the published literature about how quality criteria are viewed and applied by researchers.

Integration: an evolving concept

Integration is used definitively as a descriptive term classifying an IMMR design; however, historically, there are varying interpretations about what constitutes integration when it occurs in an IMMR design. Greene’s (2007) interpretation is that the components, namely “samples, instruments, data sets, and analyses” “interact” “or have a conversation” and this conversation illustrates the “interact[ions]” occurring across the various stages of a study (p. 125, quotations in the original). Bryman (2007) interprets integration as a “negotiated account” occurring as the findings per strand “dialog” (p. 21). Bazeley and Kemp’s (2012) joint perspective centers on the interdependent relationship existing between data collected and the

subsequent analyses of these data leading to an integrated outcome. Collins' (2015) interpretive perspective centers on expanding the concept of integration as encompassing researchers' intertwined decisions pertaining to research, sampling, and validity designs, and the transparency of these decisions prompts the credibility of the study's outcomes to research consumers. Poth's (2018) perspective is that research practice is a non-linear endeavor, and it is designed and implemented under unpredictable conditions of complexity. In her view, successful integration requires researchers to adapt their practices of research to accommodate the encountered complexity. According to Poth (2018), the points of adaptation are occurring at the conceptualization stage when the researcher is (a) formulating the rationale and purpose for the study, (b) acknowledging the role of context in design, and (c) recognizing the strengths and limitations of the individual level or group members' levels of expertise impacting their design considerations.

Across these perspectives are similarities and dissimilarities relative to the focus that each researcher places on the concept of integration as it relates to IMMR. Greene (2007) and Bryman (2007) interpret integration as a conversation or dialogue that researchers self-construct as they view the contribution of each strand to the overall research outcome. In contrast, Bazeley and Kemp's (2012) focus on the codependent relationship between data collection and analytical activities, and it is the quality of this relationship that leads to integrated outcomes. Collins' (2015) focus also is on the interdependent relationship among design decisions, namely research, sampling, and validity designs, and it is the quality of these relationships that leads to integrated outcomes. Poth (2018) focus varies from the preceding interpretations. Poth's focus is on the complexity surrounding the study, and, in response to this complexity, researchers incorporate adaptations in their decisions about the study's design and implementation.

Researchers have indicated that there are complications surrounding the concept of integration. One potential complication is the assumption that there is a shared and consistent interpretation about the metaphors used to convey integration (Bazeley and Kemp, 2012). One example is the metaphor triangulation. Archibald (2016) has observed that researchers have expressed multiple interpretations of this term within the IMMR literature. Her observation has led her to conclude that the multiplicity of these interpretations downplays triangulation's utility as a term synonymous with integration, a point also made by Tashakkori et al. (2020). Bazeley and Kemp (2012) recommend that researchers specify *how* they are interpreting the term triangulation to illustrate how integration is occurring within a study. This leads to a second complication, which is the degree that the researcher's intentionality regarding integration is transparent to the research consumer. To address this complication, Fetter and Freshwater (2015) call for researchers to embed within their designs "intentional choices that can leverage integration" (p. 116). A third complication occurs when researchers' decisions regarding design and method selections are not transparent, subsequently, weakening the argument that "researchers [have] genuinely integrat[ed] [their findings] in such a way that the quantitative and qualitative components are mutually illuminating" (Bryman, 2007, p. 8). Maxwell et al. (2015) point out that the transparency issue associated with researchers' design and method decisions in terms of their relationship to integration "often are misleading" in the published literature (p. 225). To address these complications and other potential complications, researchers can review the literature to ascertain guidelines in the form of frameworks or typologies, with the understanding that these frameworks are not absolute.

An IMMR design has the potentiality to address concurrently exploratory and confirmatory research questions leading to results that when integrated allow the researcher to draw meta-inferences or conclusions not viable when using solely a quantitative or qualitative strand (Tashakkori and Teddlie, 2008). A meta-inference denotes an inference formulated based on the integration of inferences derived from the results obtained from qualitative and quantitative strands within a study (Tashakkori et al., 2020). There are varying types of inferences. Two types defined by Tashakkori and Teddlie (2008) are inference quality and data quality. Inference quality pertains to the process of interpretation when drawing conclusions and data quality contributes to this process by the quality of the data collected, analyzed, and interpreted, thereby leading to credible meta-inferences.

Influential aspects in IMMR design are forming a rationale and purpose for conducting an IMMR design. Collins et al. (2006b) developed an empirically based framework consisting of four rationales based on the results of their content analysis detailing how IMMR designs were implemented in the published special education literature. These four rationales followed by their formulated meaning in parentheses are (a) participant enrichment (participant recruitment), (b) instrument fidelity (assessment of the appropriateness of the instrument or the creation of one), (c) treatment integrity (assessment of the intervention's fidelity), and (d) significance enhancement (acquire diverse types of data leading to elevated interpretations). Accompanying these 4 rationales were 65 purposes identified in the literature and formulated by the authors. Examples of these purposes are in parentheses (a) participant enrichment (identify reasons for attrition, optimize sample selection by acquiring data leading to participant recruitment); (b) instrument fidelity (identifying potential biases in observational protocols, or instrument measurement error); (c) treatment integrity (identify characteristics of intervention implementation, such as consistency, barriers, and expeditors); and (d) significance enhancement (expansion of results across the quantitative and qualitative strands, and the development, modification, and testing of theory). The authors' intent underlying the design of this framework was to provide empirically based examples and author's suggestions for purposes, thereby providing the impetus to consider an IMMR design.

Research design

When conceptualizing a research design, there are prescribed design criteria that exist across many design typologies such as (a) level of integration, (b) time orientation of the ordering of the strands (concurrent vs. sequential), and (c) priority placed by researchers on the results when forming inferences and generalizations. Level of integration refers to the points in the study, whereby the researcher interconnects or integrates a decision or a result occurring within one strand of the study (i.e., quantitative) with a decision or a result occurring within the other strand (i.e., qualitative), and there can be multiple points of integration. Concurrent ordering of strands indicates that there is independence between the strands implemented and integration of results across the strands occurs at the conclusion stage. Sequential ordering of strands indicates that there is a dependency between strands, whereby data collected in one strand informs decisions implemented in a subsequent strand. When interpreting results per strand, the researcher decides as to how the analyzed data will be prioritized when drawing integrated conclusions. Factors that influence these decisions are the sample strategy used to collect these data per strand, sample size per strand, and the research question guiding the study's design. Examples of generalization choices are statistical generalization, internal statistical generalization (Onwuegbuzie and Leech, 2009), internal generalization (Maxwell, 2021), case-to-case transfer supported by theory (Creswell and Poth, 2017; Firestone, 1993), analytic or theoretical generalization (Yin, 2018), naturalistic generalization (Stake, 2005), and moderatum generalization (Payne and Williams, 2005). These criteria form the foundation of the design typologies of Onwuegbuzie and Leech (2009), Creswell and Plano Clark (2017), and Tashakkori et al. (2020). Guest (2013) makes the point that these typological design criteria focus on the study as a whole and are rudimentary because they cannot accommodate all types of design considerations occurring in more complex studies.

Other researchers offer an alternative interpretation of design. Guest (2013) recommends design criteria that involves the researcher focusing only on the "*point of interface*" occurring when data are integrated across the strands and to include two descriptive dimensions, namely timing and purpose of data integration (p. 146, italics in the original). Onwuegbuzie et al. (2013) introduce their conceptualization of design as context-specific, and it is based on their adaptation of Bronfenbrenner's (1979) ecological systems model. This model consists of four environmental contexts, and each context affecting differentially a person's development. Onwuegbuzie et al. (2013) adapted these four levels relative to the design of IMMR, namely (a) *micro-research studies* Level 1, that involves research focused on the individual or group within their current environmental context, (b) *meso-research studies* Level 2, that involves research focused on the individual or group selection of an environmental context that they choose to spend time, (c) *exo-research studies* Level 3, involves research focused on the individual or group choice of a context that they might be affected but it does not represent a context where the individual or group participates as an active member, and (d) *macro-research studies* Level 4, represents a cultural or societal context in which the individual or group participates as a member. In accordance with Onwuegbuzie et al.'s (2013) conceptualization, these levels are interconnected, and research design can be expanded to encompass more than one level.

Sampling design

A sampling design consists of the researcher's choice of sampling scheme and the determined sample size per strand. The choices of strategy and size reflect the interdependent relationship among research question, research design, and validity design. Additionally, these choices also are influenced by the practical aspect of balancing the collection of adequate data to address the research question and the available resources to implement the study. Using the existing literature as a source, Collins (2010) identified five criteria obtained from the published literature to consider when determining the sample design. Applying criterion 1 the researcher considers the dependent relationship between the sample per strand and the time orientation of the research design (concurrent or sequential). Applying criterion 2, the researcher indicates that the sampling unit per strand reflects the relationship between the strands. In this context, the sampling design could include an *identical* (same individuals participate in all strands of the study), *nested* (a subset of the sampling units in strand 1 is the sampling unit for strand 2), *multilevel* (the samples participating in the strands have a different level of engagement with the variable of interest [e.g., teachers, students, and the variable of interest is learning]), and *parallel* (different sampling units participate in the strands but the samples are drawn from the same population [e.g., different teachers participate in the strands]). Applying criterion 3, the researcher recognizes that the sampling unit selection is predicated on the relationship between the specific scheme selected and the type of generalization chosen by the researcher. Applying criterion 4, the researcher's selection of sampling units is predicated on choosing units that can produce multiple forms of data, such that the different data types can elevate the interpretation of the variable of interest. Applying criterion 5 the researcher is cognizant that the sample size can impact the degree of priority that is placed on the type and amount of data collected per strand and the integration of results across strands. This decision regarding priority is influenced by the type of generalization chosen by the researcher, sample design per strand, and the research question. Interpretive consistency refers to the relationship of the sampling design per approach, the emphasis placed by the researcher on the results of both strands, and the degree that integration leads to credible and defensible meta-inferences (Collins and Onwuegbuzie, 2013; Collins et al., 2006a). Interpretive consistency can be compromised when the design decisions pertaining to the sequencing of the strands (concurrent or sequential) leads to unintended order effects or the sample size per strand is not taken under consideration when forming the decision to place more value on the results of one strand (comprising a larger sample size) in contrast

to the results generated by another strand (comprising a smaller sample size), thereby making integration problematic (Onwuegbuzie and Johnson, 2006). Subsequently, the transparency of researchers' decisions pertaining to sampling design is a critical quality criterion in IMMR studies (Collins et al., 2012).

Validity design

A critical dimension of IMMR design is the rigor of the quality criteria embedded throughout the study (Onwuegbuzie and Johnson, 2006). The design, application, and evaluation of quality criteria that reflect standards of rigor identified by intellectual communities is referred to as a validity design (Collins, 2015). Crafting a validity design requires researchers to... "select and use the appropriate quality criteria for the particular research questions and for the particular research study" (Collins, 2015, p. 245). Constructing a validity design requires that researchers be cognizant of several points. The first point is the choice of language used to convey the dimensions of the design. Language descriptive of quality criteria varies across quantitative, qualitative, and IMMR. The choice of language is likely to be reflective of the researcher's engagement with specific intellectual communities. For example, rigor of the design in a quantitative strand is interpreted by researchers as validity, reliability, replication, and consistency (Campbell and Stanley, 1963). The language describing rigor in a qualitative strand centers on trustworthiness that comprises the following attributes: dependability, confirmability, credibility, and transferability (Lincoln and Guba, 1985). The choice of language will influence the degree that the validity design is viewed as credible by the research consumer at the study's dissemination stage. Second point is the alignment of the quality criteria and the researchers' intended generalizations of the integrated results is an important component of a validity design.

Selective quality criteria frameworks

There are several quality criteria frameworks available to researchers to assist in designing quality criteria for their IMMR study. The frameworks detailed in this section were selected because each framework presents a different perspective about the design of quality criteria. It is important to recognize that each framework and each criterion presented in the framework are not absolutes. Rather the frameworks and the quality criteria are guidelines for researchers to reflect upon when developing the specific quality criteria pertinent to their individual study.

Onwuegbuzie and Johnson (2006)

Integration within an IMMR design can blur the distinctive lines classifying quality criteria associated with a specific strand. To address this complication, researchers can design and apply legitimization criteria, a term coined by Onwuegbuzie and Johnson (2006), to distinguish quality criteria pertinent to the unique design considerations of an IMMR study. Actualizing this perspective into practice, the researcher applies legitimization criteria to address potential threats. Onwuegbuzie and Johnson (2006) identified nine potential design threats. The name of each threat is presented in the parentheses. First threat deals with the degree that the researcher's choices regarding sampling decisions relative to the sample design per strand facilitates formulation of credible meta-inferences (sample integration). Second threat notes the degree that there is clarity in the expressed views of the researcher and the participants in the forms of description, explanation of the data, and the conclusions (inside-outside). Third threat is the degree that the weakness or limitation of one strand in terms of providing adequate data is addressed by the design quality of the other strand (weakness minimization). The potential impact of an order effect occurring by the researcher's choice to implement one strand prior to the implementation of the other strand (sequential) is the fourth threat. Fifth threat is the degree of the quality of the data as a result of the transformation of data as in the cases of qualitzing and quantitizing (conversion). Qualitizing is a process whereby quantitative data are converted into data that can be analyzed using qualitative methods. Quantitizing is a process whereby qualitative data are converted into data that can be analyzed using quantitative methods (Onwuegbuzie and Teddlie, 2003). Sixth threat is the degree that a researcher's philosophical beliefs, such as "epistemological, ontological, axiological, methodological, and rhetorical" (p. 57) that underpin the researcher's decision to integrate results into a cohesive and credible meta-inference that supports their choice of design (paradigmatic mixing). The degree that the "meta-inferences made by the researcher reflect a mixed worldview based on the cognitive process of Gestalt switching and integration" (p. 57) (commensurability) is the seventh threat. The eighth threat pertains to the degree that the researcher has implemented appropriate quality criteria associated with quantitative, qualitative, and IMMR throughout the study, thereby leading to the formulation of credible meta-inferences (multiple validities). The ninth threat pertains to the degree that the research consumer values the meta-inferences formulated by the researcher when integration of the results occurs across the strands (political).

Tashakkori et al. (2020)

The integrative framework conceptualized by Tashakkori et al. (2020) is based on two interrelated quality standards. The first, design quality, focuses on the degree that the methods selected and the design of the strands pertaining to the "conceptualization, experimental methodological/analytical [and] inferential" decisions (p. 145) address appropriately the research question.

Underpinning design quality is design fidelity that addresses the rigor of the design accompanied by the appropriate methodological implementation of the design and procedural decisions. Design quality also is supported by design consistency and analytic adequacy. Design consistency reflects the degree that the strands are implemented in a “logical and seamless manner” and analytic adequacy is addressed by the execution of data analysis techniques that will address appropriately the research question (p. 301). Interpretive rigor, as a quality standard, examines the relationship between the inferences drawn by the researcher and the type of consistency noted in parentheses (a) “type, scope, and intensity” of the findings (interpretive consistency) (p. 301); (b) “theory and state of knowledge in the field” (theoretical consistency) (p. 301); (c) researcher’s conclusions also are considered viable by other researchers (interpretive agreement); (d) conclusions determined by the researcher are credible in contrast to other possible conclusions (interpretive distinctiveness); (e) researcher’s meta-inferences are supported by the conclusions (integrative efficacy); and (f) meta-inferences formed by the researcher are related to the purpose of the study and the research question, thereby supporting an IMMR design (interpretive correspondence).

Hall and Howard (2008)

Another example of an integrative framework is the synergistic framework designed by Hall and Howard (2008). Their synergistic approach to the design of quality criteria comprises four core principles. Researchers applying these four principles acknowledge that researchers’ philosophical assumptions and stances when applied to the design of quality criteria can support an IMMR design, application of quality criteria representing qualitative and quantitative traditions are viewed as equitably important in obtaining credible outcomes, integration of these multiple quality criteria can lead to credible outcomes that are potentially superior to and definitively different from outcomes derived from implementing a singular strand to design, and researchers can apply an inter-subjective approach toward interpreting claims, thereby balancing equitably claims about subjectivity and objectivity. The concept of synergy also underpins Fetter and Freshwater’s (2015) perspective on integration, and their call for researchers to identify the synergy that occurs when integrating across the qualitative and quantitative strands within an inquiry.

Collins et al. (2012)

Collins et al. (2012) incorporated Hall and Howard’s (2008) synergistic framework along with aspects of other published legitimization frameworks (e.g., Creswell and Plano Clark, 2017; Dellinger and Leech, 2007; O’Cathain et al., 2008; Onwuegbuzie and Johnson, 2006; Tashakkori et al., 2020) into a legitimization framework that is built on the premise that quality criteria in the context of an IMMR design is a “continuous, holistic, and synergistic process” (p. 855). Collins et al. (2012) introduced two additional quality criteria. These two criteria serve as their framework’s core elements. Philosophical clarity, as the first quality criterion, refers to the degree of awareness, on the part of the researcher, of their paradigmatic assumptions and equally important their awareness of the degree that these assumptions influence design decisions and create opportunities for obtaining credible conclusions and successful integration. The second quality criterion aligns with Collins et al.’s (2012) perspective that legitimization criteria are enhanced when researchers ... “dialogue with values [and] perspectives of multiple communities of practice” and concomitantly these two criteria ... “play continuous, iterative, holistic, and synergistic role in the legitimization process” (p. 849). In this context, process refers to researchers embracing the concept that the design of quality criteria occurs throughout the study and at the study’s conclusion, thereby leading to credible and defensible meta-inferences.

O’Cathain (2010)

O’Cathain (2010) developed a quality criteria framework consisting of aspects of the published literature. The framework was organized into the following sub-categories: (a) stage of the study, (b) domains of quality, (c) items within the domains, (d) definition of each item per domain, and (e) published source of domains and items. Quality domains identified by O’Cathain are (a) planning quality, (b) design quality, (c) data quality, (d) interpretive rigor, (e) inference transferability, (f) reporting quality, (g) synthesizability, and (h) utility.

Selective validity design concerns

Although constructing a validity design sounds intuitively logical to designing quality criteria, in the context of IMMR, O’Cathain (2010) queries the researcher’s dichotomous choice to design and to implement quality criteria tailored to the “methodological strand or to each method used” (p. 535, italics in the original). This choice is impacted by the decision to implement a sequential design involving interdependency between strands, the decision to implement multiple methods of data, and the decision to implement data conversions (quantitizing, qualitzing) (O’Cathain, 2010). A second concern is that integration of findings across strands blurs the distinction between strands and compromises the integrity of quality criteria designed per strand (O’Cathain, 2010). A third concern is the degree of the researcher’s degree of self-awareness of their philosophical stance and the influential impact it has on methodological decisions (Collins et al., 2012).

Selective empirical examples of validity designs

In this section, I outline selective examples of validity designs obtained from published studies. These examples were selected because the (a) the researcher was transparent in detailing their design decisions pertaining to research, sampling, and validity designs; (b) in the write-up of the study, they applied published quality criteria applicable for addressing potential threats to integration; and (c) the research centered on a topic relevant to the field of education. In the following outlined studies, the specific framework that guided researchers' decisions is noted as a header.

Onwuegbuzie and Johnson (2006)

Study 1. [Ivankova \(2014\)](#) applied a three-step procedure with a specific focus on procedures associated with implementing these steps and were accompanied by strategies that were designed to validate meta-inferences and to address validity threats in designing and implementing a sequential design. The goal of this study was to illustrate these procedures in practice, subsequently, they were applied in a study of graduate students' skill acquisition in applied research online courses. The ordering of the strands was quantitative followed by qualitative. The rationale for conducting a sequential design was that this type of design requires strategies crafted to address potential order effects of strands, which, subsequently, might impact the integration process.

The sample was a nested sample ([Onwuegbuzie and Collins, 2007](#)). In the quantitative strand, the sample comprised 84.5% ($n = 119$) of students who had completed at minimum of one of the four on-line research courses. In the qualitative strand, data collection consisted of telephone interviews containing 12 questions and selective probes that were designed to illicit more information per question. The sample was a purposive sample of 13 participants who had participated in the quantitative strand and were selected using a maximum variation sampling scheme. The resulting sample of students' interview responses were coded into the following categories: typical, extreme, unique, and the students represented a combination of varying levels of demographic status.

The validity design focused on implementing a three-step procedure. First step and second step were implemented by applying separate criteria aligned with specific research communities' standards and the type of data collected ([Bryman, 2006](#)). Specifically, step 1, the numerical data analyzed were questionnaire data and the analyses implemented were reliability coefficients, descriptive statistics, ANOVA, and multiple regression. In step 2, qualitative data were analyzed using a constant comparison method ([Glaser and Strauss, 1967](#)). Third step a contingency strand was applied, whereby quality criteria were designed based on the individual characteristic of the study's design ([Bryman, 2006](#)). Actualizing this step required application of strategies aligned to the design of a sequential IMMR design. The nested sample strategy (i.e., a subset of participants participated in both strands), thereby supporting sample integration, whereby the quality of the meta-inference is not compromised by introducing in one strand a sample that differs from the sample in the other strand ([Onwuegbuzie and Collins, 2007](#)). This study employed a sequential design that allowed [Ivankova \(2014\)](#) to assess the interaction of the trends noted in the results of the quantitative strand (strand 1, questionnaire data) and then explain these findings in the analysis of the data collected in the qualitative strand (strand 2, interview data). The integration of findings across the two strands led to an emerging design, whereby [Ivankova \(2014\)](#) expanded the number of questions in the telephone interview protocol and collected more data while the study was in progress. Triangulation for the purpose of corroboration of the qualitative findings occurred by examining three sources of data: interview data, follow-up emails, and the interviewers and Ivankova's reflective notes. Also, member checking was implemented to establish the credibility of the transcribed interviews and intercoder agreement on the results of the content analysis was measured on the themes (94%) and the codes (89%). In this study the three-step procedure supported the credibility of the meta-inferences formed from the conclusions integrated from both strands in a sequential design.

Onwuegbuzie and Johnson (2006)

Study 2. The goal of the study conducted by [Bustamante \(2019\)](#) was to assess professional development of teachers who were integrating Web 2.0 technologies into the Spanish curriculum in grades 7–12 in the context of online courses. Web 2.0 technologies that are included in the professional development are "blogs, wikis, podcasting, and poster, video, or comic generators" ([Bustamante, 2019](#), p. 165).

The rationale for conducting an IMMR design was significance enhancement ([Collins et al., 2006b](#)), whereby quantitative and qualitative strands are implemented to broaden the researcher's perspective on the topic of interest. Specifically, [Bustamante's \(2019\)](#) comparative purpose for conducting an IMMR design was to assess similarities and dissimilarities in the results of the data analyzed and to facilitate integration by implementing joint displays to visually merge data to facilitate interpretation and integration as recommended by [Guetterman et al. \(2015\)](#). Bustamante implemented joint displays to connect her results to a theoretical model, namely the Technological Pedagogical Content Knowledge (TRACK) model. This step is viewed as an "innovative" strand to design by Guetterman et al. ([Bustamante, 2019](#), p. 164, quotations in the original). The research design was a convergent design, whereby data in the forms of numerical and textual data were collected independently, and the results were integrated when forming meta-inferences. This design was selected because it allowed Bustamante to assess to what extent did the qualitative results confirm the quantitative results. Qualitative data comprised interviews, observation protocols, group discussions, documents, weekly journal entries, and final essays written by the participants detailing their experiences. Qualitative data were analyzed and coded to produce themes. Quantitative data, in the form of numerical questionnaire responses, were obtained at three points

in the study: pre-post-and follow-up tests. Quantitative data were analyzed using descriptive statistics, and ANOVA. The sample consisted of an identical sample (Onwuegbuzie and Collins, 2007). The quantitative strand consisted of 18 participants and 17 of the 18 participants were interviewed in the qualitative phase of the study, thereby addressing the threat of sample integration (Onwuegbuzie and Johnson, 2006).

Convergent quality criteria were implemented per strand (Bryman, 2006). Specifically, the analyzes were aligned to the type of data collected. A circular joint display was developed to facilitate data merging and integration. The joint display portrayed the following three components that were aligned to the TRACK theoretical model guiding Bustamante's decisions: (a) technology, (b) pedagogy, and (c) content. Bustamante (2019) also applied the list of potential validity threats identified by Creswell and Plano Clark (2017). Adherence to this list of their proposed strategies, Bustamante (2019) reported applying the following quality criteria strategies (a) implementing separate data collection procedures per strand and applying separate criteria aligned with type of data collected, (b) applying a joint display to illustrate visually the dissimilarities and similarities of the results leading to successful integration., Member checking also was implemented to confirm accuracy of the data collected and the degree that the results had face validity.

Tashakkori et al. (2020)

Study 3. Reid Kerrigan (2014) implemented a study to assess the potential impact of the application of data-driven decision making (DDDM) on the organizational capacity of community colleges. The rationale for implementing an IMMR design was significance enhancement (Collins et al., 2006b). Specifically, implementing qualitative and quantitative strands allowed Reid Kerrigan to ask confirmatory and exploratory questions, and as noted by Tashakkori et al. (2020) asking both types of questions within a single study is one of the defining characteristics of an IMMR design. The purpose for the collection of qualitative and quantitative data was that it permitted the development of an integrative analysis of quantitative and qualitative data, leading to an integrative data set, thereby providing a broadening of interpretation of a relationship between DDDM and organizational capacity of community colleges. The research design by Reid Kerrigan (2014) was a convergent parallel design implemented by applying a multiple case design. Application of a multiple case design allowed Reid Kerrigan to conduct a cross-case analysis. Application of a maximum variation sampling strategy permitted selection of colleges at two levels, top third and bottom third, in terms of their capacity for data use. The sampling design was a nested sampling design involving state selection ($n = 2$) by applying a critical case sampling scheme college selection ($n = 4$) by applying a maximum variation sampling scheme. Selection of administrators to participate was by invitation and faculty participants were randomly selected. The sample participating in the quantitative strand comprised full-time administrators ($n = 120$) and faculty ($n = 151$) employed at four colleges. Quantitative data consisted of collection and analysis of questionnaire data. The sample participating in the qualitative strand consisted of a subset of administrators and faculty who participated in the quantitative strand and who could provide "insight about data use" ($n = 38$) and who were selected using a criterion-based sampling scheme (p. 348). The validity design comprised reported reliability coefficients for questionnaire responses. A scheme to ensure consistency of the coding of the qualitative data was implemented, and inter-rater reliability to assess the level of consistency between coders was reported. Applying quality criteria recommended by Tashakkori et al. (2020), Reid Kerrigan (2014) addressed design suitability (convergent parallel design was appropriate to address the research questions), design fidelity (data collection and analyses procedures were aligned to ensure consistency with the design parameters), and analytic adequacy (detailed reporting supporting the adequacy of the data analysis to address the research questions).

O'Cathain (2010)

Study 4. Collins (2018) conducted a 4-phase analysis of the Reid Kerrigan (2014) study, Collins' intention was to detail the points of integration noted in the write-up of the study and to comment on the degree of transparency surrounding Reid Kerrigan's decisions relative to the design, method, analyses, and the points of integration in the write-up of the study. Collins (2018) concluded that Reid Kerrigan (2014) addressed the following transparency quality criteria identified by O'Cathain (2010): rationale and planning transparency, design transparency, data transparency, interpretive transparency, and reporting transparency.

Selective aspects of designing quality criteria

I conclude this section by presenting selective perspectives about the design of quality criteria obtained from the literature. Bryman's (2006) review of the literature identified three general perspectives expressed by researchers regarding quality criteria. The first viewpoint is to apply convergent criteria, and it involves applying these criteria to all strands. The second viewpoint is to apply separate criteria by employing quality standards embraced, for example, by the post-positivist research community (validity [internal external], reliability) and the constructivist research community (trustworthiness, transferability). These standards drive the construction of quality criteria to align the method of collection and the analysis of data collected per respective strand. The third viewpoint is to apply a contingency approach to designing quality criteria. Implementing this approach involves the researcher designing quality criteria based on the individual study; specifically, the design is centered on the level of integration and the degree that the findings obtained from one strand is prioritized appropriately when forming conclusions.

More recently, Fabregues et al. (2019) examined how quality criteria are conceptualized and procedurally implemented by researchers within an IMMR design. Their design was a multiple case design. Fabregues et al. (2019) selected a criterion sample of international researchers ($n = 44$) who represented the disciplines of education, nursing, psychology, and sociology. Participants were asked, via semi-structured interviews, for their opinions about how to conceptualize and implement procedurally quality criteria within an IMMR design. Data analysis consisted of a thematic analysis of the participants' responses and a within and cross-case analyses to detect potential patterns within the data set. Trustworthiness of the results was established by participants' member-checking the transcriptions of the collected data. Peer-debriefing interviews of the authors by a peer not associated with the study but who had familiarity with IMMR, were implemented. Peer debriefing interviews can serve to explore potential biases and to broaden researchers' understanding of the overall research process, and it is a form of an audit trail that is a recommended quality criterion by Onwuegbuzie et al. (2008). Additionally, data were collected to document methodological and analytical decisions and reflections made by Fabregues et al. (2019). These analyzed data also served as an audit trail. Results indicate that the quality criteria mentioned more than five times by the respondents were: (a) rationale for the IMMR study, (b) clarity of the purpose and the research questions, (c) clarity of the design in terms of phasing of the strands and the integration process, (d) clarity of the quality criteria reflected in the respective strands, (e) compatibility of the strands in terms of addressing the intent underpinning the study, (f) alignment of the inferences to the study's findings and inconsistencies noted, (g) transparency in the write-up of the study in terms of clarity and detail leading to credible and defensible inferences, and (h) the relevant IMMR literature was detailed in the write-up of the study.

Results indicated that published quality frameworks were favored by most of the participants. There were differences based on the participants' disciplines about the format of these frameworks. Educationalists and sociologists tended to favor frameworks that were "highly flexible [and] adaptable to different research contexts" (p. 435). In contrast, psychologists and nursing preferred a check-list format, specifically containing "criteria in the form of closed questions or scoring systems, highly structured, and that aimed at generating objective measurements of quality" (p. 435). The degree of familiarity with the frameworks was split. Half of the participants expressed familiarity with published frameworks, albeit a small number of frameworks, namely, the frameworks of Tashakkori and Teddlie (2008) and O'Cathain (2010). Advantages of frameworks from the perspective of those participants were their perceived utility in summarizing critical aspects of the IMMR literature and the practical component of detailing guidelines for implementing and appraising IMMR. Criticisms were centered on the degree that a framework can capture the complexity and dynamic interactions surrounding the IMMR study. As noted by Fabregues et al. (2019), there were points of convergence between the frameworks' content, and, subsequently, the literature on quality criteria. However, also noted by Fabregues et al. (2019) is that it is beyond the scope of this inquiry to determine the cause for this convergence. They ask the question Is it "the result of existing frameworks reflecting researchers' views on the quality IMMR or vice versa?" However, the convergence within this sample of 44 researchers suggests that the frameworks *potentially* impacted these researchers' views on quality criteria.

Conclusion

This chapter began with a definition of high-quality research. The goal of this chapter was to prompt the design of high-quality research by discussing quality criteria within the context of IMMR. The premise guiding the writing of this chapter was that the complexity of an IMMR design requires researchers to address issues of validity not required within a monomethod study. As a context for interpreting quality criteria in an IMMR design, I discussed the concept of integration by presenting selective and historically scholarly interpretations of integration within the IMMR and to emphasize the evolving nature of integration in the IMMR literature. I presented the concept of inference as it relates to design decisions within an IMMR by detailing design approaches leading to credible and defensible meta-inferences. Selective approaches to designing quality criteria, obtained from the published literature, presented in the form of selective frameworks were outlined to guide researchers' decisions when crafting quality criteria for a particular study. Also outlined, as exemplars of successful validity designs, were selective examples of empirical perspectives obtained from the published literature about how quality criteria are conceptualized and applied by researchers. I hope that the content of this chapter can inform researchers' future decisions in designing quality criteria for their studies.

Glossary

Collective reflexivity Engagement as a group in an active, ongoing process of critical reflection of how researchers co-construct knowledge from and during the research team process based on their identities, experiences, subjectivities, ontologies, and epistemologies

Ethical reasoning Decision-making in response to a moral dilemma based on a careful and thorough assessment of the different options in light of the facts, circumstances, and ethical issues (Poth, 2021)

Ethical review Consideration which intends to protect research subjects by minimizing the harms or risks to which they are exposed during research activities. The process often takes place within a community, an organization, or an institution

Informed consent A free and informed decision such as to participate in research. Individuals who provide informed consent must be legally competent and have enough decision-making capacity to consent to research

Mixed methods research An approach requiring the integration of both quantitative and qualitative data which assumes that their collective contribution mitigates inherent weaknesses in either type of data (Poth, 2018a)

Polyvocalism/polyvocality Incorporating more than one distinct authorial voice or perspective during reporting (Creamer, 2018)

Reflexive practice/reflexivity Engagement in an active, ongoing process of critical reflection of how the researcher constructs knowledge from and during the research process based on their identities, experiences, subjectivities, ontologies, and epistemologies (Cain et al., 2019)

Research ethics Application of ongoing thought and judgment of the fundamental ethical principles to the planning and implementation of research often guided by three principles: respect for persons, concern for welfare, and concern for justice.

Introduction

The conduct of ethical research is essential to protect participants, researchers, and society (Poth, 2021). Considering that ethical issues can arise at any time, researchers in educational settings need to be prepared for their ethical responsibility to respond appropriately. Ethical reasoning can offer important decision-making guidance in response to a moral dilemma based on a careful and thorough assessment of the different options in light of the facts, circumstances, and ethical issues (Anderson and Corneli, 2018). The need for ethical reasoning within a mixed methods research approach can be intensified by the requisite integration of qualitative and quantitative data and team configurations that are useful for tackling pressing societal issues in

education (e.g., Curry et al., 2013; Mertens et al., 2016; Poth, 2019). That descriptions of the unique ethical dilemmas faced by researchers and teams remain underdeveloped presents a key challenge for mixed methods researchers to engage in ethical reasoning. This chapter extends the assertion that unique ethical issues arise from integration in mixed methods research and leads us to offer promising practices to address that, “more so than using a single method design, mixed methods research yields the potential for complex and even amplified ethical problems” (Preissle et al., 2015, p. 157).

When investigating complex problems, mixed methods researchers often encounter dynamic or unstable research conditions which complicate the implementation of predetermined research plans. Key among the challenges for mixed methods researchers conducting research under conditions that are considered complex involves providing sufficient evidence in a proposal to satisfy the expectations of a supervisory committee as well as institutional, community, and organizational ethical review boards. The dynamic nature of a study means it is often impossible to fully predetermine the required elements such as participants, procedures, and expertise. We argue there is a pressing need to describe the unique ethical dilemmas related to integration that are encountered by mixed methods researchers and to offer practical guidance for how researchers and teams engage in ongoing ethical reasoning to realize the principles of ethical research under dynamic research conditions.

This chapter leverages our collective mixed methods research and team experiences to contribute practical ethical guidance in three ways: (1) by introducing the ongoing ethical reasoning necessary when engaging in the requisite integration of qualitative and quantitative research, (2) by illustrating why navigating three unique ethical dilemmas encountered by mixed methods researchers becomes intensified under dynamic conditions and team configurations, and (3) by describing three ethical practices including the use of reflexivity to guide mixed methods researchers managing the complexity inherent in ethical reasoning.

Rationale for focus and description of team approach to this chapter

To provide practical guidance reflecting the conditions mixed methods researchers are likely to encounter during the requisite integration of qualitative and quantitative research, we focus the promising practices on our experiences with dynamic conditions and team configurations. Our use of the term *teams* in this chapter includes the dissertation committees supporting graduate students, even though the literature on educational mixed methods research teams has not explicitly acknowledged this team configuration. Our own use of a team configuration for writing this chapter recognizes the enhanced capacity of mixed methods research teams for drawing upon members’ unique capacities for addressing more complex societal problems (e.g., Curry et al., 2013; Mertens et al., 2016; Poth, 2019).

To this work, Poth brings extensive expertise and experience as an educational mixed methods researcher diagnosing and managing dynamic mixed methods research conditions (Poth, 2018a,b), advancing mixed methods research team practices (Poth, 2012, 2019), and examining research ethics (Poth, 2021; Stadnick et al., 2021). Creamer brings extensive expertise and experience offering practical guidance for fully integrated mixed methods research (Creamer, 2018), intersections of different methods (Creamer, 2021), and reflexivity (Creamer, 2011). As an emerging mixed methods research scholar, Cain brings expertise about reflexive practice as a key component of ethical reasoning in mixed method research (Cain et al., 2019). Throughout the conceptualization and writing of this chapter, the team met regularly to move the chapter forward and create conditions for the emergence of new insights that would otherwise have been inaccessible by each researcher alone.

Challenges introduced by the inherent complexity in ethical reasoning within mixed methods research and teams

All research in education is guided by three principles for the conduct of ethical research: respect for persons, concern for welfare, and concern for justice (Anderson and Corneli, 2018; Poth, 2018a). The wording of these principles may vary by country, but their meaning remains the same. Fig. 1 provides a summary of the principles along with the questions researchers should ask themselves (Poth, 2021). The researcher is primarily responsible for the conduct of ethical review of their research and one way researchers can be supported in their efforts is to have an ethical review board review their research plan. Ethical reviews can take place in several ways, and more than one may be necessary: (1) a student’s supervisor and dissertation committee provide feedback on the research proposal (2) research undertaken through an institution (e.g., research center or university), likely needs approval from an institutional review board, and (3) research within a community or organization might need approval from those bodies. Consider that anticipating all the ethical issues that might arise unexpectedly in a well-articulated research proposal is unlikely so researchers must also be prepared to respond appropriately throughout the research.

Conducting mixed methods research in education can be challenging in addition to being rewarding and researchers need to be prepared to respond appropriately to ethical issues. There are often limitless possibilities for investigators with diverse methodological expertise to pursue research in education (Poth, 2019). According to the American Educational Research Association (AERA, 2021), education research involves:

[T]he scientific field of study that examines education and learning processes and the human attributes, interactions, organizations, and institutions that shape educational outcomes. Scholarship in the field seeks to describe, understand, and explain how learning takes place throughout a person’s life and

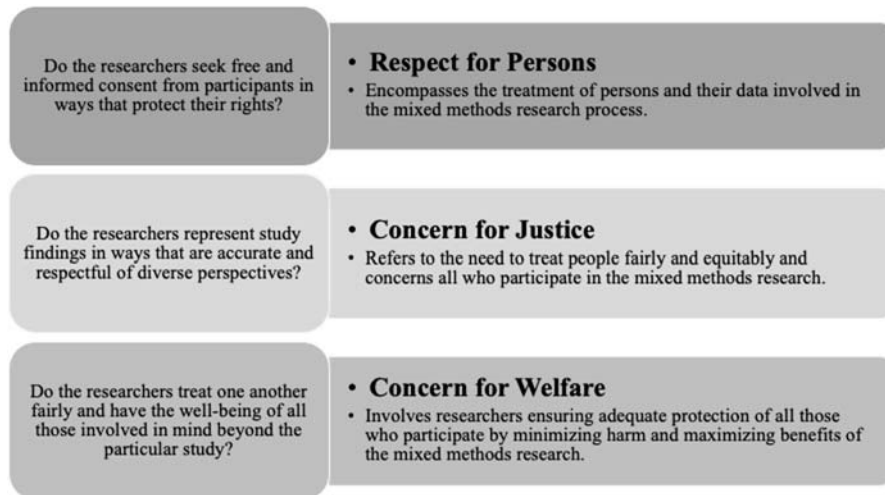

Fig. 1 Three principles for the conduct of ethical research.

how formal and informal contexts of education affect all forms of learning. Education research embraces the full spectrum of rigorous methods appropriate to the questions being asked and also drives the development of new tools and methods.

Research pursuing complex educational issues often benefit from team configurations drawing upon diverse disciplinary and methodological expertise.

Many of the inherent challenges when forming a mixed method research team with differing perspectives, experiences, and assumptions are well documented in the literature (Curry et al., 2013). These may become intensified under conditions of increased complexity and require new ways of interacting to leverage these differences productively (Poth, 2019). Many of our conventional approaches to methodological training restrict opportunities for meaningful interaction across disciplines and research approaches. They perpetuate the idea that research conditions are stable and that it is necessary to silo research methods. The training challenge noted by Hesse-Biber (2016, p. 650; emphasis in original) is that:

... researchers *do not practice interdisciplinarity well*. This is because, in part, they do not actively seek out ways to tap into the potential synergy of a team-based mixed methods project. They ethnocentrically do not see past their own comfort zone or horizon for theories, questions, and methods. I further argue that there is a *lack of conscious reflexivity* on the part of the research team; instead, the team often buys into the idea of 'inherent' synergy contained in these types of research configurations and designs. *Working in a group does not necessarily mean that you are working as a team.*

On teams, processes that allow for collective reflexivity can advance ethical practice by contributing to the methodological transparency that is necessary to share responsibility for ethical decisions that are made across the areas of responsibility of different team members.

Attending to ethical issues requires careful planning before conducting educational research, ethical actions during the mixed methods research process, and appropriate responses to emerging issues as the research process unfolds. Fig. 2 represents the iterative plan, act, and respond cycle to realize the principles of ethical research that is continually informed by ethical reasoning. Researchers must assume that ethical dilemmas can arise at any time throughout the research process and the conduct of ethical research requires ongoing thought and judgment specific to each mixed methods research project (Preissle et al., 2015). The need for ongoing ethical reasoning informed by reflexivity throughout the research is intensified in cross-disciplinary teams working in dynamic mixed methods research environments.

As a pillar of qualitative research, reflexivity is a practice that engages researchers in making explicit what they bring to study decisions and how they influence them. Glesne (2011) posited that reflexivity involves "critical reflection on how researcher, research participants, setting, and research procedures interact and influence each other" (p. 151). Popa and Guillermin (2017) applied the usefulness of these reflexive concepts to teams when they argued that "reflexivity can facilitate meaningful and problem-specific ways of combining methods across different disciplinary fields, types of expertise, and practices" (p. 19). We argue engaging in critical reflection about the many lenses educational researchers bring to a study and how they interact with topics, participants, data, and team members is essential for the conduct of ethical mixed methods research.

Fig. 2 Iterative plan, act, and respond cycle to realize guiding principles of ethical research.

Ethical dilemmas arising from integration in evolving designs

As a key characteristic of mixed methods research, the requisite integration of qualitative and quantitative research introduces unique ethical dilemmas in need of attention throughout the research process. Of paramount importance for meeting quality criteria for mixed methods research is to provide evidence of integration in the designs, procedures, and reports (Creamer, 2018; Fàbregues and Molina-Azorín, 2017; Onwuegbuzie and Poth, 2016; Plano Clark and Ivankova, 2016). For these reasons we have chosen to focus on three dilemmas arising from integration that we have ourselves experienced and observed others' experiencing with some frequency. For each, we describe the ways that changing research conditions and team configurations can intensify the unique ethical dilemmas and what is often considered an appropriate response.

Reasoned expectations of participation burdens

As is the case for all research, mixed methods researchers must respect participants' rights to know what is expected of them and to ensure that researchers seek free and informed consent throughout integration procedures. Providing full information about the mixed methods study to potential participants is key to demonstrating the ethical principle of *respect for persons* yet it can be especially challenging with sequential or longitudinal designs. Among the key challenges in predetermining research plans and consent procedures when research involves plans that build upon one another (i.e., sequential) or in designs where researchers may need to attend to the evolving needs of participants because the procedures occur over time (i.e., longitudinal). Common to both of these scenarios is that participants may be involved in multiple qualitative and quantitative data collections points in sequential or longitudinal research and that the protocols can evolve. For example, an interview protocol for a followup qualitative phase cannot be completely predetermined in a sequential design at the beginning because it is informed by the quantitative survey findings from the initial phase.

Similarly, protocols in longitudinal designs often evolve over the course of the study. Rare accounts of how researchers adjusted their procedures in response to their populations were described by Plano Clark et al. (2015) as part of an examination of longitudinal mixed methods designs from the health sciences. Whereas Wallen et al. (2012) replaced a long quantitative measure with a semi-structured qualitative questionnaire for palliative care participants, Symons et al. (2012) communicated through text messaging to be less intrusive to new parents. It is important that procedures be in place for participants to know and to have opportunities to reevaluate their consent to participate voluntarily once they become aware of the expectations, withdraw participation and data at any time, and clarify their understanding of participation with the researchers.

When we consider our experiences and observations, we note that attending to team members' and participants' vulnerability informs our ongoing ethical reasoning. Challenges can arise when working as a team where close coordination is required to develop a shared understanding of the consent processes individuals will be expected to follow across all phases of the study. Considering participant vulnerability and capacity is also essential to providing consent because research in education often involves working with vulnerable populations (such as school-aged children) within workplace settings where participants (e.g., teachers, principals) could be subject to coercive practices.

Comprehensive representation of integrated findings

The ethical *concern for justice* principle requires all researchers to report evidence and procedures honestly and in ways that respect diverse perspectives. Burch and Heinrich (2016) describe a fully integrated approach to mixed methods as including adaptability to the uncertainty and variability of complex designs as well as collaborators regularly and intensively discussing their data and findings. Ethical issues can arise from differing interpretations of the data. Unique to mixed methods research, reconciling divergence between the qualitative and quantitative phases can be problematic. Such challenges provide examples of how interpersonal context can introduce significant ethical challenges in mixed methods research (Plano Clark and Ivankova, 2016), especially after a project is underway (Hesse-Biber, 2010).

From our own experiences, we see the challenges of competing results causing tensions among researchers as relating to fairness with important consequences for how mixed methods researchers present their study outcomes. Some researchers have turned to publishing qualitative and quantitative findings in separate manuscripts which can mislead the reader and circumvent complexity by oversimplifying the outcomes of integration (Archibald et al., 2015). Searches for disconfirming evidence and exploration of alternative explanations about the same evidence is part of the process of warranting findings during reporting (AERA, 2006) and we argue these processes inform ongoing ethical reasoning in mixed methods research. The resulting tension poses a challenge for methodological transparency in mixed methods research (Evans et al., 2011; Hesse-Biber, 2010; Macfarlane, 2010; Popa and Guillermin, 2017) and for meeting expectations in reporting standards (Onwuegbuzie, 2012).

Reasoned reporting of authorship contributions

Establishing a fair way to designate contributions during reporting is a challenge encountered by all researchers. Attention is needed to meet the ethical principle of *concern for welfare* of all those involved in the research. This ethical issue can become pronounced when using mixed methods, when researchers actively integrate their methods during different phases of a research project (Hesse-Biber, 2010). Areas of responsibility and ownership of ideas are more readily determined in mixed methods projects when there is a clear division of labor that parallels areas of expertise.

When we consider our own research experiences, we note that attributing responsibility for ideas is more difficult to disentangle in a setting where there is a fluid division of labor or a high level of interaction, and that this is a dimension of ethical reasoning. This challenge is intensified in an integrated or dialectical approach to mixed methods that puts the emphasis on a back-and-forth between different methods throughout the research process (Creamer, 2021). For many researchers—and, in particular, those building their scholarly record in order to secure a job or funding—authorship, and even the order of authorship, can have high-stakes implications for professional well-being.

Three promising practices for addressing ethical dilemmas in integration

To advance the discussion of and illustrate real-world applications of ethical reasoning for managing the ethical dilemmas we have described, we offer three promising practices related to the design of integration procedures, the implementation of integration strategies, and the communication of integration outcomes. For each of the promising ethical practices, we describe the nature of the unique ethical dilemma intensified under dynamic mixed methods research conditions and team configurations. We also discuss the role that individual and collective reflexivity plays in managing the complexity inherent in ethical reasoning and offer examples of reflexive questions to guide mixed methods researchers in generating self-understanding and shared understandings among team members.

Design integration procedures that affirm free and informed consent

The requisite integration procedures within sequential, emergent, and evolving mixed methods research designs introduce the potential to intensify the time and expectation burdens placed on participants. Common across the designs are integration procedures that cannot be entirely predetermined because the follow-up phase of the research builds upon the results of the initial phase. Consequently, it can be impossible to provide fulsome information about the study procedures to participants at the onset as normally required to meet the standard of free and informed consent. With participants potentially vulnerable to increased time and expectation burdens introduced by some of the research designs, reflexivity offers the opportunity for researchers to individually and as a team to weigh their expectations of participants. This collective reflexive practice is noteworthy because it allows team members to develop a shared understanding of what might be asked of participants during the different phases of the research. These discussions have important consequences for developing consent procedures that inform participants about how initial consent will be sought and possibly reaffirmed later in the process. Of particular importance, engagement in individual and collective reflexivity enables researchers to interrogate procedural decision-making involved in the implementation of mixed methods research designs.

We have considered participant burden in our educational mixed methods research designs involving teams and changing conditions. Poth recalls having to adjust her team's expectations of school-based participants in a follow-up phase in response to the sudden shift to remote learning during the COVID-19 pandemic (Georgiou et al., 2021). Poth's ongoing discussions with

her interdisciplinary team to build a shared understanding of what could be reasonably expected of classroom-based participants helped communicate the impact of the shift to remote learning and to convey these changes to participants as the research unfolded.

Guidance for mixed methods researchers to attend and mitigate participant burden remains an understudied yet timely topic for further study. A survey involving 64 scientists conducting mixed methods health services research provides compelling evidence for this pressing need: Participant burden was the most frequently occurring ethical issue and among the most challenging one identified (Stadnick et al., 2021). It should also be noted that informed consent was the least reported ethical issue. Together with a limited focus of strategies that mitigate shortening data collection instruments, this evidence points to the pressing need for attention on consent procedures within mixed methods research. Similarly, experience tells us that, when working in teams, it can be a common practice for some researchers to be more involved in some aspects of the data collection and analysis involved in integration, and potentially not at all such aspects. A shared understanding of the expectations of how recurring consent procedures are implemented in practice is necessary to meet the standard for respect of persons as a guiding ethical principle. The following reflexive questions are offered to guide mixed methods researchers in affirming free and informed consent to generate self-understanding of their perspectives and build shared understandings among mixed methods research team members:

- How do my/our previous experiences influence my/our thinking about what research procedures I/we consider to be reasonable expectations for participants? How might my/our conceptualizations of “reasonable” differ from those among the research team members and participants?
- What would evidence of free and informed consent look like from participants throughout the research process? Do the research plans offer adequate protections for potentially vulnerable participants to provide consent?
- How do the research procedures provide adequate opportunities to ensure free and informed consent from participants during each data strand or phase? How might participants be affected by sequential, emerging, and evolving research designs and procedures and how can researchers keep participants adequately informed and reaffirm consent?

Implement integration strategies that authentically acknowledge multifaceted findings

The availability and use of several integration strategies make it possible to account for differences in findings or interpretations that emerge during mixed methods research without necessarily exceeding the word limits of a journal article. The differences can be important points for discussion and linked to various literature in a manuscript. Interestingly Pluye et al. (2009) describe that such points of divergence are frequently mentioned in reports, yet they rarely become the focus of analysis and integration. Common under dynamic and team conditions are integration outcomes that cannot be entirely predetermined because the data procedures may evolve and because of the contribution of interdisciplinary perspectives on the data that is generated. Consequently, it can be impossible to predict the nature of the integration outcomes. A table or figure can provide important opportunities for graphic techniques to acknowledge and represent variations in the strength of support for different constructs or paths that depict the relationships between them. Kawamura et al. (2009) offer an example of how textual symbols or shading can be used to signal elements of a figure where the qualitative and quantitative data are not consistent. An additional strategy is to introduce polyvocality (also recently called polyvocality) in the text (Creamer, 2011) involves acknowledging that team members could not reach consensus about the findings. These strategies have important consequences for developing integration strategies that acknowledge multifaceted findings. Of particular importance, engagement in individual and collective reflexivity enables researchers to interrogate what each individual brings to the integrated findings and the decision-making involved in the generation of meta-inferences or integrated insights.

In our own implementations of integration strategies throughout our educational mixed methods research, we have considered multifaceted findings in our integration strategies involving teams and dynamic conditions. Creamer recalls once having to navigate the political realities of a situation where research for a federally supported program to advance gender equity disclosed unpleasant realities about what had actually been accomplished. An additional example involves Poth having to broaden her team’s approach to integration in a study comparing teachers’ responses to items about personal responsibility for student motivation quantitatively and qualitatively because of unexpected divergence in findings and initial interpretations (Daniels et al., 2018). Having engaged in collective reflexivity with her interdisciplinary team to build a shared understanding of how the different disciplinary cultures and training among team members might influence their perspectives helped decisions about what and how to represent and discuss the multifaceted study findings as the research unfolded.

Dissemination of project results was the second most frequently occurring ethical issue reported by Stadnick et al. (2021), and the *most* challenging. Yet there was no discussion of effective strategies for addressing this. Similarly, our team’s experience and review of literature reveals that divergence as well as convergence in findings is to be expected and welcomed (Bazeley, 2018) and that authentic reporting is necessary to meet the ethical standard of *concern for justice* as a guiding ethical principle for ethical mixed methods research. The following reflexive questions are offered to guide mixed methods researchers in acknowledging multifaceted findings to generate self-understanding and shared understandings among mixed methods research team members:

- How are my/our decisions throughout the research process affecting the study findings? Have I/we included enough information so that a reader can understand and replicate the study?

- Have I/we shared enough information about my/our epistemological commitments and background experiences so that readers can understand which lenses I/we brought to the data interpretations? Have I/we given enough weight and value to each team member's epistemological views in our analysis and integration procedures?
- How are my/our decisions about which findings to include and how to organize the findings reflected in the final manuscript? Have I/we adequately protected the identities of our participants in our findings?

Communicate integration reports that fairly recognize contributions

The involvement of various researchers working under dynamic mixed methods research conditions introduces challenges for authorship when dissemination plans are emergent. The ethical principle guiding the *concern for welfare* extends to protecting the intellectual contributions of researchers in addition to protecting participants from harm and respecting the confidentiality or anonymity of the data they provide (Poth, 2021). Common under dynamic team conditions are opportunities for new ideas for publications and audiences to emerge during discussion of emerging results; yet, at the same time, additional challenges can be introduced when there is an undervaluing of individual contributions and power dynamics among team members. Specific complications for mixed methods research teams involve a lack of understanding of the time- and resource-intensive nature of the requisite integration and emergent processes (Curry et al., 2013; Sharp et al., 2012).

The contributions acknowledged by authorship often have to be renegotiated as a project unfolds because they cannot be entirely predicted at the onset of the reporting phase. It is important to highlight that authorship can be complicated and is not the only way to acknowledge contributions in mixed methods research. It is common to recognize editorial or minor contributions through a footnote or endnote. The practice of adding transparency to reporting through an endnote about the roles, perspectives, and contributions of team members is one strategy that helps a reader or audience member gauge the ownership for new ideas and original insight. Such approaches to communication have important consequences for fairly recognizing contributions. Of particular importance, engagement in individual and collective reflexivity enables researchers to interrogate what each individual brings to the work and authorship decision-making involved in the fair recognition of report contributions.

In our own communication of integration reports within our educational mixed methods research, we have considered fair recognition of authorship in our designs involving teams and dynamic conditions. Poth recalls having to adjust her educational team's authorship on a health-focused methodological contribution in the *Journal of Mixed Methods Research* to responsively involve a public health researcher in the manuscript (Poth et al., 2021). This means that teams should shift their practice to forming teams that can adapt to evolving understandings of the expertise that is needed as a project unfolds (Poth, 2019). Having engaged in collective reflexivity with her interdisciplinary team to build a shared understanding of how the team membership might be in flux and the impacts of that on authorship helped decisions about whom to involve as the research unfolded. The following reflexive questions are offered to guide mixed methods researchers in authentically recognizing contributions to generate self-understanding and shared understandings among team members:

- How do my/our previous publication experiences influence my/our thinking about what contributions I/we consider to be reasonable expectations for authorships? How might my/our conceptualizations of "reasonable expectations" differ from those among the research team members?
- To what extent and how was each team member involved in the design, implementation, analysis, and writing phases of the study? Have I/we considered the power dynamics that exist within the team and how they affect the work each person does?
- Has each team member been given an opportunity to weigh in on authorship order? How might my/our conceptualizations of authorship order differ from other team members'?

Concluding thoughts

Our impetus for this work was the lack of practical guidance for addressing the unique ethical dilemmas arising from integration and intensified by the complexity inherent to evolving mixed methods research designs and interdisciplinary team configurations. We welcomed the opportunity to describe promising ethical practices that addressed dilemmas we observed and experienced in our interactions with colleagues and graduate students in our varied roles as mixed methods researchers, instructors, team members, and dissertation supervisors. Our collaborative work on this chapter to advance three promising ethical practices leverages our collective expertise and experiences in diagnosing and managing dynamic mixed methods research conditions, research ethics, reflexivity, and research teams. We encourage others to do the same and to expand the descriptions of ethical dilemmas experienced beyond the three ethical practices described here and importantly, for others to learn from, the promising practices guiding successful navigation. A key takeaway points to the need for preparing mixed methods researchers to respond appropriately to ethical dilemmas as the research unfolds and to ethical reasoning informed by individual and collective reflexivity as central to the promising practices described in this chapter.

Acknowledgments

The chapter advances new insights and extends ideas we have previously published separately (e.g., Cain et al., 2019; Creamer, 2011, 2018, 2021; Poth, 2018a,b, 2019, 2021; Poth et al., 2021). We thank Adrienne Montgomerie for helpful comments on the draft manuscript. We are grateful for the opportunity to contribute to this encyclopedia and thank our colleagues from around the world who continue to influence our thinking as well as our Volume editor Dr. Nataliya Ivankova and the editors-in-chief for guiding this chapter through to publication.

Mixed methods in educational evaluation

Program evaluation is a field that shares much common ground with applied research, however, it has developed as a separate discipline because of the political context in which evaluation is conducted (Mertens and Wilson, 2019). The purpose of evaluation is to inform decision making and to support sustainability of interventions, such as programs, policies, products, processes or plans (Mertens and Tarsilla, 2015). Evaluation in education is sometimes thought of as a method to determine the effectiveness of programs, however, evaluation can play a broader role when data are collected to identify important contextual factors (contextual analysis), need for improvement or changes in practice (needs assessment), or the quality of implementing an intervention (process evaluation). Because educational evaluation is conducted in the messy, political world of schools and agencies, many complex issues can arise and a wide range of people can be impacted by the interventions (known as stakeholders). The use of mixed methods in educational evaluation provides a means to address the complex, political, and human issues in this context.

Distinction between evaluation and research

Research and evaluation can look very similar, especially if the research is conducted to address a specific problem, such as effectiveness of an educational intervention. Both disciplines rely on the collection of systematic data to understand the phenomenon. The purpose of research has been defined as the collection of data to construct theory or create knowledge (Mertens, 2020). Thus, researchers can choose the context and focus of their studies based on their intellectual interests. The purpose of evaluation is to inform decision making and support sustainability of an intervention (Mertens and Wilson, 2019). Evaluators conduct their studies at the request of a stakeholder group (e.g., a funding agency, program director, policy maker, or community representatives) in contexts of resource scarcity, leading to competition for program support. The evaluator needs to be able to negotiate this political landscape through appropriate inclusion of stakeholders and provision of data viewed as credible by those stakeholder groups. To answer this challenge, many evaluators have turned to the use of mixed methods. The relationship between mixed methods research and evaluation in education is displayed in Fig. 1.

In this chapter, the evolution of the paradigms in educational evaluation is described. The assumptions of the five dominant paradigms (post-positivist, constructivist, pragmatic, transformative and Indigenous) in educational evaluation are presented. This is followed by examples of the design of mixed methods studies in educational evaluation for each paradigmatic perspective in order to demonstrate the impact of the evaluator's assumptions on methodological choices.

Paradigm wars and current landscape of philosophical frameworks in evaluation

Humans engage in evaluation activities everyday when they make decisions about what to eat, which movie to watch, or what to wear. However, the profession of evaluation was formally established in the United States in the 1960s because the government began to require evaluation of programs that were funded under Lyndon Johnson's Great Society initiatives. Many other countries have followed suit and evaluation is now a global practice. Evaluation's roots are very multi-disciplinary, reflecting eclectic methodological approaches. Evaluations conducted in its infancy years tended to rely on quantitative designs and methods that were informed by the postpositivist paradigm (Mertens and Wilson, 2019). However, qualitative methods were introduced to the evaluation community largely through the scholarly work of Guba and Lincoln (1989). The introduction of qualitative methods into this profession stirred up great controversy about the best methods for conducting evaluations; this period is known as the

Fig. 1 Relationship between mixed methods research and evaluation in education.

“paradigm wars.” However, Guba and Lincoln were able to establish a way forward by explicating the concept of paradigm frameworks to make clear that decisions about quantitative or qualitative methods were based on fundamental assumptions about the nature of ethics and values (axiology), reality (ontology), value of knowledge and relationships with stakeholders (epistemology), and systematic inquiry (methodology). The assumptions thus drive the methodological decisions.

The evaluation community operates with five different paradigmatic frameworks: Postpositivism, constructivism, transformative, pragmatism, and Indigenous (Chilisa and Mertens, 2021; Chouinard and Cram, 2020; Mertens and Hesse-Biber, 2013; Mertens, 2018; Mertens and Wilson, 2019). Mixed methods can be applied to evaluations conducted within all of these paradigmatic frameworks, however, the assumptions associated with each lead to different decisions regarding the use of mixed methods. Briefly, postpositivists prioritize the use of quantitative methods with qualitative methods playing a supportive role (White, 2013). Constructivists prioritize qualitative methods with quantitative methods serving a supportive role (Hesse-Biber, 2010). Transformative evaluators rely on qualitative methods to build culturally respectful relationships across stakeholder groups and to understand the experiences of the full range of stakeholders in a culturally complex context (Mertens, 2018; Mertens and Wilson, 2019). These methods are combined with quantitative data to provide a fuller understanding of context and program effectiveness. Pragmatic evaluators use methods that they deem are necessary for answering the evaluation questions (Creswell and Plano Clark, 2018). Indigenous evaluators also prioritize building respectful relationships that are culturally responsive in order to make visible the legacy of colonialism and its continuing impact on the lives of Indigenous peoples (Chouinard and Cram, 2020). Quantitative methods can be included in Indigenous evaluations in order to understand context, track progress, and demonstrate effectiveness. The sections that follow provide examples of evaluations that are conducted using mixed methods within each of the five paradigmatic stances.

Designing mixed methods studies: different perspectives

Postpositivism and mixed methods

The postpositivist assumption of ontology, the nature of reality, is that there is one reality that exists and the evaluator needs to be able to measure that reality with a certain level of certainty. Thus, the choice for data collection tends to be a quantitative measure that has a known level of reliability and validity. The postpositivist epistemological assumption rests on the belief that evaluators need to be objective, defined in terms of not engaging with stakeholders in order to prevent personal biases from affecting the study. The preferred mixed methods design under this paradigm is a randomized control trial (RCT) when feasible and a quasi-experimental design if necessary. The quantitative data are prioritized and the qualitative data serve a complementary role.

White (2013) argues that postpositivism is the best framing for a mixed methods study because it prioritizes obtaining an answer to what he considers the most important question: Did the intervention work? He sees opportunities for integrating the collection of qualitative data into an RCT design in order to understand the appropriateness of recruitment strategies and to document the implementation process of the intervention. This question of fidelity of treatment, i.e., is the intervention being implemented as planned without making changes, is often answered through the collection of qualitative data (Mertens, 2020). This is necessary to ensure that the intervention that was implemented is the same intervention that was hypothesized as being an effective way to address a problem.

Edmunds et al. (2021) conducted a mixed methods study that was framed by the post-positivist paradigm. They used a RCT design to determine the comparative effectiveness of sections of a course that had the goal: “to increase the number of students, particularly students of color, completing online courses and improve the academic performance of those students, with the ultimate goal of increasing the percentage of students who remained in postsecondary education (p. 5).” The original plan for the research was to randomly assign students to course sections that were taught by instructors trained in the intervention and control instructors who taught as they normally would. In this part of the study, quantitative and qualitative data were collected by a survey with both open and closed ended questions that students completed. The researchers also collected quantitative data on Blackboard participation and outcome variables (e.g., course completion). Additional qualitative data were collected via interviews with staff.

The results of this first phase revealed: “The evaluation found that the intervention had overall (on average) statistically significant impacts on reducing withdrawals and positive, although not statistically significant, impacts on successful course completion (Edmunds et al. p. 2).” However, the researchers were intrigued by the finding that the results differed considerably when comparing the two experimental sections to each other. This finding led them to add a second phase to their study which provides further illustration of using a postpositivist framework to a mixed methods evaluation in education because they wanted to understand why the intervention seemed to work in one section and not the other. In addition to re-analyzing the data collected in the first phase, the researchers collected new quantitative data on the instructor characteristics and qualitative data through observations and interviews with staff. They found that students in Section A had significantly more log-ins for Blackboard than students in Section B. This analysis allowed them to have a comparative measure of exposure to the treatment in the two experimental sections. The observational data were collected by reviewing videos of the instructors’ uses of the experimental treatment strategies in their lectures. Section A instructor incorporated more of the treatment strategies than did Section B instructor; this exemplifies a mixed methods approach to process/implementation evaluation. This finding was supported by the interview data with the staff who reported differential use of the treatment strategies. The researchers acknowledged that a limitation of their study was that they did not interview the students, thus, they did not have the students’ perspectives of the course implementation and effectiveness. The researchers also discussed a very practical problem: they were not able to randomly assign instructors to the sections because one of the instructors in the experimental group had designed the intervention.

The logic of RCT is based on the prioritization of objectivity, control, standardized procedures and measurements, and maintaining distance between the program participants and the evaluators. Embedding a qualitative component into a study can create tensions because a truly interpretive framing would require an open-ended, emergent, close relationship between evaluators and participants. Logistical reasons can also prevent researchers from including a strong qualitative component, as Edmunds et al. (2021) noted, they had not planned to do the second stage of their study and they had very limited resources to carry out the second phase. Thus, the use of mixed methods under the postpositivist paradigm requires sacrifice of the assumptions of a constructivist approach to mixed methods. Mixed methods under the constructivist paradigm is specifically designed to address issues of context and participant experiences.

Constructivism and mixed methods evaluation

Evaluators can conduct their inquiries using only qualitative approaches, thus reflecting the core assumptions of the constructivist paradigm. However, evaluators have tended to combine the use of qualitative and quantitative methods in order to be responsive to the multiple stakeholders and to answer the different kinds of evaluation questions. Evaluators who work within the constructivist paradigm tend to design mixed methods studies that prioritize the qualitative methods and use quantitative data in a supportive role (Mertens and Hesse Biber, 2013). As constructivists, evaluators use more sophisticated and detailed qualitative designs, such as adaptations of ethnographic methods or case studies.

Loizzo et al. (2018) conducted a qualitatively driven mixed methods evaluation of a Massive Open Online Course (MOOC) in journalism for social change. The course was designed to increase journalism students’ knowledge of how to mobilize citizen journalists around social justice topics. The intervention was a 7-week MOOC that was offered at a university in the United States. The course was developed by the instructors who were interested in documenting the strategies they used to teach the course, as well as the successes and challenges they experienced. They wanted to know what the students identified as successes and challenges in the course and how it affected their attitudes toward constructivist journalism for social justice. The major focus of the study was on the experiential data for instructors and students, therefore, qualitative data collection was dominant. The evaluators used a mixed methods design that incorporated virtual ethnography and a quantitative survey. Virtual ethnography is used to study online communities to understand their cultures and interactions. The data collection methods consisted of overt observations of the MOOC on a weekly basis, collection of screen captures of artifacts used by the instructor, and review of documents such as syllabus, curriculum materials, student assignments, instructor announcements, and discussion posts. They also conducted interviews with the instructor and five of the learners two weeks after the end of the course. The interviews were conducted via email and Skype.

The quantitative portion of the study consisted of an email survey designed to assess the students’ attitudes. The responses were made using a 5-point scale. The results of the survey were analyzed and the means and standard deviations were reported. The qualitative data were analyzed using open codes through which categories emerged such as MOOC purpose, passionate and motivated instructor and students, and child welfare context. The evaluators presented the findings using constructivist practices of explaining the codes that emerged and providing exemplary quotations from the documents, interviews, and observations to support the relevance of the theme. They were also able to identify several challenges in learning through the MOOC format that provided opportunities for feedback to the instructor on modifications to improve the course. They integrated the survey findings into the

presentation of the qualitative themes to support the students' positive attitudes toward the course and applying the concepts that they learned.

Gubrium et al. (2016) provide another example of a constructivist mixed methods evaluation in their assessment of the effects of a digital storytelling intervention on the self-esteem, social support, and sexual attitudes of Puerto Rican girls. Digital story telling asks participants to create a short narrative account of a relevant life event using digital images, audio recording, music and text. The creation of the digital story is accomplished through small-group workshops. The process used in digital storytelling consists of individual work to write a script, collect images, and record. This is followed by a group process that is co-mediated by facilitators and work group members. Another group process phase occurs in the form of a story circle and story screening. The evaluation focused on the process and effect of these workshops held in a city with high health risks and poverty. Quantitative data were collected using established psychosocial measures. They reported that very little evidence of effectiveness was produced by the quantitative measures perhaps because these measures are not able to capture the effects of a process that involves writing, storytelling, visual representations, sound and voice, and esthetics. However, the qualitative data revealed vibrant positive changes and health benefits for the participants.

An ethnographic approach was used for the qualitative component of the study. Evaluators observed and assisted with each workshop; they created field notes; and the sessions were audiotaped. In addition, the evaluators conducted interviews with each participant. The documents for analysis included transcripts from the workshops, story circles and story screenings, interview transcripts, field notes, debrief meetings, and participant responses to a workshop evaluation. The evaluators concluded that the emphasis on the qualitative component of the study was appropriate given the cultural context and the demographics of the target population. They were able to demonstrate positive changes in self-esteem, social support and sexual attitudes through the words and images of the participants.

Pragmatism and mixed methods evaluation

Evaluators work in the real world; they encounter challenges that might preclude the use of a RCT or a rich qualitative approach. Pragmatism is characterized by the logic that evaluation methods should be chosen that will allow the evaluator to answer the prescribed questions. Thus, some questions can be answered with qualitative data, others with quantitative data, or at times, both types of data are needed. These evaluation questions in the pragmatic paradigm are generally generated by the funding agency in consultation with program staff and the evaluation team. Akerblad et al. (2020) used this lens to frame their mixed methods evaluation of vocational rehabilitation programs in Finland. The purpose of the study was to evaluate the "implementation and effectiveness of the rehabilitation model and its effects and benefits from the perspective of the service participants, workplace, occupational health services and rehabilitation service provider" (p. 7).

It should be noted that under this lens, the intervention was already decided by the rehabilitation specialists and the evaluation questions were set before the evaluation team entered the picture. The questions are derived from the purpose: How was the program implemented? How effective was the program for the different stakeholder groups? The evaluators developed a mixed methods design to answer these questions for their client. The data to answer the implementation question came from individual and group interviews with the human resource specialist, occupational health service providers and rehabilitation service providers. The data on effectiveness was gathered using quantitative questionnaires before and after the intervention; these were administered to service participants, supervisors and health service providers. The data from the various sources were analyzed separately before the quantitative and qualitative data were put into conversation with each other. The quantitative data were given priority and the qualitative data were interpreted within that framework. The results indicated that the supervisor played a critical role in insuring that the multiple actors collaborated effectively. The use of this mixed methods design answered the client's questions; it did not provide rich contextual information that is typically generated when a constructivist lens is used, as was described previously in this chapter. In the next section, the use of mixed methods from a transformative stance illustrates how prioritizing issues of justice and culture influences methodological choices.

Transformative mixed methods and evaluation

Postpositivist, pragmatic, and constructivist evaluators design their studies to align with their assumptions. They can, but are not compelled to, consider the issues of power and inclusion of members of marginalized communities. In the education sector, marginalized communities include people of color, Indigenous community members, sexual minorities, people who are disabled or Deaf, refugees, immigrants, and students from high poverty areas. Addressing issues of power, historical inequalities, cultural responsiveness, inclusion of the full range of stakeholders, and designing evaluations to support increased social, economic, and environmental justice are fundamental principles for transformative evaluators (Mertens, 2018, 2020; Mertens and Wilson, 2019). These are issues that educators know are important for sustainable change.

Transformative mixed methods evaluations utilize a cyclical approach that begins with a first phase of relationship building across the full range of stakeholders, with particular attention to groups who have historically been marginalized (See Transformative Mixed Methods, Fig. 1, Mertens, in this volume). Evaluators may need additional time to figure out the best way to work with the full range of stakeholders in order to demonstrate cultural responsiveness, consciously address issues of power, and provide safe environments for sharing knowledge and experience that comes from people with lived experience in the communities. This phase

of relationship building is a qualitative process that needs to be evaluated for inclusiveness and culturally responsive working strategies.

The relationship building phase leads to a phase for contextual analysis that includes collection of both qualitative and quantitative data in order to understand the history, political structures, economic conditions, heterogeneity in the populations, incidence data, and any other relevant indicators such as educational or employment characteristics. The results of these first two phases are used as the basis for the development or refinement of an intervention that can then be pilot tested using intensive collection of both quantitative and qualitative data on the strategies used for recruitment, training, implementation, barriers, challenges, strategies for overcoming barriers and challenges, and effectiveness of the piloted intervention. The data from this phase can be used to make refinements to any aspect of the intervention or to make decisions to try something quite different if the pilot is not successful. Once an intervention is viewed as appropriate in a given context, then it can be implemented on a wider scale with quantitative and qualitative data collected on variables similar to those used during the pilot testing. Qualitative data reveals the process of implementation and the quality of experiences. Quantitative data can reveal participation rates and effectiveness measures. Finally, the evaluation needs to include the use of the process and impact data for transformative purposes, e.g., refinement or change of intervention, changes in policies, and strategies to strengthen relationships.

Culturally responsive approaches in evaluation are commensurate with the transformative paradigm (Bledsoe and Donaldson, 2015). Drill et al. (2017) used a transformative mixed methods approach with a culturally responsive lens in their evaluation of a project titled "Bars to Bridges." The project was designed to support students of color who were in the juvenile justice system in their transition back into regular school. The multi-phase cyclical study began with building relationships with school personnel, juvenile justice agents, community organizations, families, and youth (See Fig. 2). The evaluators did not assume that they knew what evaluation questions to ask or how to collect data. In keeping with the transformative culturally responsive approach, they formed discussion groups with these stakeholders to formulate evaluation questions and develop data collection strategies. They conducted a contextual analysis that involved collection of data on relevant legislation (qualitative) and disproportional rates of discipline practices by race based on extant quantitative data. This first phase that included the collection of both quantitative and qualitative data (concurrent mixed methods) led them to identify diverse stakeholders who needed to be included and gave direction to their next data collection phase.

The project staff developed an intervention based on the data collected in the first phase of the evaluation. The second phase of the evaluation was primarily qualitative and included examining the quality of relationships with the students, reviewing program documents, and conducting interviews and focus groups with a conscious awareness of the importance of being culturally responsive with the full range of stakeholders. The data from the second phase documented the primary activities and the challenges and successes in implementing the intervention. The evaluators also collected data on the extent to which the stakeholders viewed the intervention and the evaluation as being culturally responsive. The evaluators collected quantitative and qualitative data concurrently in the third phase to establish the quality of the experience for the students, transition specialists in the schools, and the juvenile justice personnel. The quantitative data consisted of extant data on such variables as recidivism and school attendance. The evaluators consciously employed the process and results of their study for transformative purposes. They raised the need to address attitudinal barriers that prevented a smooth transition back into the schools, as well as other logistical barriers. They also met with state level policy makers to develop a state-wide protocol for school re-entry.

Fig. 2 Transformative mixed methods cyclical design of bridges to bars project (Drill et al., 2017).

Indigenous mixed methods evaluation

Indigenous and transformative evaluations share many commonalities; however, Indigenous scholars have identified important differences (Chilisa and Mertens, 2021; Cram and Mertens, 2015; Cram et al., 2013). One important difference is that Indigenous evaluators recognize the critical impact of a legacy of colonialism that contributes to current inequalities (Chilisa, 2020, 2015). All Indigenous scholars are not the same; uniqueness is associated with different Indigenous groups and also within Indigenous groups. Indigenous scholars from the United States (Lafrance and Nichols, 2010), Africa (Chilisa, 2020), and Aotearoa (New Zealand) (Cram and Mertens, 2015; Cram et al., 2018) provide different perspectives based on their countries of origin. However, they do share the demand that they have the authority to define problems, solutions, and evaluation strategies that are culturally appropriate for their own communities. Culturally responsive Indigenous evaluations can use many different methodologies, e.g., participatory, community-based, and tribal participatory methods can be used, as long as they are practiced through an Indigenous lens (Chouinard and Cram, 2020). An Indigenous lens requires a contextual analysis that reflects the history of colonialism, including genocide, racism, expropriation of land, and suppression of Indigenous knowledge.

Hamerton et al. (2012) conducted an evaluation of a program designed to encourage changes in behavior toward a healthier lifestyle in Aotearoa New Zealand. The program was located in communities that served the Maori population because quantitative data indicated that members of this community manifest greater health disparities than in the White communities and that programs that had been imposed on Maori had not been effective. The goal of the program was to support healthier eating and exercise choices based on information from the community itself. Thus, the Healthy Eating Healthy Action program was begun by providing funding to six Maori health agencies who worked with community members and health experts to develop interventions built on cultural values and practices that could be delivered with close connection to the communities. Although the study was implemented in health agencies, it has implications for educators who are concerned with addressing healthier life choices by their Indigenous students. The plans included activities to improve nutritional knowledge, increase physical activity, educate particular groups, and reduce obesity.

The evaluation used an Indigenous lens in the form of Kaupapa Maori, or by, for and with Maori (Cram et al., 2018); the evaluators were both Maori and non-Maori. The evaluation began by spending considerable time building relationships with the evaluators, community health agency staff, and other members of the Maori community. This meant they met face-to-face with the stakeholders, visited the programs, and listened carefully to their experiences. They conducted a contextual analysis that included collection of qualitative and quantitative data. The quantitative data included measures of physical activity and individual health indicators such as weight, blood pressure, and BMI. The qualitative component of the design consisted primarily of interviews and focus groups; they followed Maori custom of bringing healthy food to these data collection events. They consciously included opportunities for reciprocity in the evaluation by sharing information with the stakeholders about successful initiatives. The data collection instruments incorporated the 4-sided model of Maori health that includes body, mind and emotions, spirituality and extended family. Focus groups looked at not only individual benefits, but also benefits that accrued to families, community, and tribe.

The results indicated that the knowledge gained and behavioral changes made by older members of the community were valued by younger members. The communities began to support local gardens that gave them access to healthier foods. This resulted in healthier food being served in community centers as well as in schools. As the program was developed within communities and they were privy to the results as they emerged, the health agencies assumed greater control and responsibility for modifying the interventions as they gained insights. This is an indicator of sustainable change because of community ownership.

Conclusion: mixed methods evaluation is multi-disciplinary and multi-perspectival

Evaluators come from many different disciplines, such as education, psychology, sociology, health, social work, economics, and business. Thus, its history is replete with the use of different types of designs and data collection methods that are associated with these different disciplines. Many of the issues faced in the educational system require interdisciplinary solutions. Mixed methods approaches provide a model for working across disciplines for these types of problems. The growth of mixed methods enhances the evaluation community's ability to examine the assumptions that drove methodological decisions. The current status of having five paradigms that inform mixed methods evaluators is viewed as a rich opportunity to learn more about methodologies. Rather than having arguments about the incommensurability of different paradigms, scholars who situate themselves in each of these paradigms incorporate quantitative and qualitative methods that align with their assumptions. Evaluators in the postpositivist and pragmatic paradigms tend to accept that their responsibility is to collect data that is responsive to their client (funder). Evaluators in the constructivist paradigm are more inclined to ask about the range of stakeholders and how their methods can provide a rich picture of the program under study. Transformative and Indigenous evaluators are more likely to stress the importance of building relationships with the full range of stakeholders and incorporating quantitative and qualitative data into the design in order to understand the cultural complexity of the community of stakeholders. They are also more inclined to use the data from earlier stages as support for the development of an intervention that is culturally responsive and to answer evaluation questions that are of importance across the stakeholder groups. The conversations across paradigms within the context of the use of mixed methods provides fertile ground for growth in understandings of effective methodologies in educational evaluation.

Glossary

Case study research a predominately qualitative approach to educational inquiry that is dedicated to developing in-depth understanding of one or more cases that represent bounded systems (Creswell and Poth, 2018; Yin, 2018)

Intersecting the intentional combination of the assumptions, designs, and methods of two distinct research approaches to form a hybrid approach to research (Plano Clark and Ivankova, 2016)

Mixed methods case study research an approach to educational inquiry that mindfully combines the assumptions, designs, and methods of mixed methods research and case study research in ways that integrate the qualitative and quantitative findings to generate enhanced knowledge of the case(s) under investigation (Guetterman and Fetters, 2018; Plano Clark et al., 2018)

Mixed methods research an approach to educational inquiry that combines at least one qualitative method (textual data) and one quantitative method (numeric data) within a single study such that the two types of data and analysis are brought together to respond to the study's aims (Johnson et al., 2007)

Introduction

There are many circumstances in education where it is beneficial to have a comprehensive understanding of the complexities of what happened in a particular situation. For example, teachers could benefit from knowing what happened when other teachers incorporated a new technology into their classroom during a semester. Student affairs officers could benefit from a description of a social justice program implemented over two years on a campus experiencing racial tensions. Educational policymakers could benefit from a comparison of what happened in different countries in the first three months following the occurrence of a health crisis. Each of these examples highlights a complex situation occurring within a system of people over some period of time where practical knowledge about what happened is needed.

To study complex real-world situations such as these, educational researchers have a wide range of research approaches from which to choose. Among the choices, some educational researchers are drawn to mixed methods research approaches, which provide a comprehensive understanding by combining quantitative and qualitative information about a complex situation (Creswell and Plano Clark, 2018; Johnson and Onwuegbuzie, 2004). At the same time, other educational researchers are drawn to case study research approaches, which provide an in-depth description and interpretation of a complex situation in one or more settings (Stake, 1995; Yin, 2018). Given the relevance of both mixed methods and case study approaches for examining the complex situations of interest in education, it is perhaps unsurprising that an increasing number of educational researchers choose to combine mixed methods research and case study research in their studies. With the increasing use of such combinations, educational

researchers, practitioners, policy makers, and other stakeholders interested in educational issues need to consider how these two approaches can be productively combined in research studies as well as understand how to identify and assess research that uses both mixed methods and case study research.

To address this need to understand and critically evaluate the combined application of mixed methods and case study research approaches to examine educational situations, this chapter discusses important assumptions and considerations involved when scholars combine the two research approaches in their studies. We begin by formally defining the two approaches separately before introducing frameworks that describe different perspectives for how the two approaches can be combined within educational research studies. We then present key decisions that go into designing a study combining mixed methods and case study research and that are useful for understanding and evaluating the study approach. From there, we highlight several examples of applications in education where mixed methods and case study were combined. We conclude by offering future directions for mixed methods case study in education and recommendations for educators interested in reading, reviewing, and conducting research using mixed methods and case study.

Defining mixed methods research and case study research

Before discussing the combined use of mixed methods research and case study research, it is essential that they each first be defined. This is no easy task as both of these methodologies have long histories influenced by scholars from different disciplines and with different perspectives about research. Here we limit the focus to definitions that are commonly accepted and applied within education and emphasize aspects most salient to considering how the two approaches can be combined in research studies. Readers interested in more complete treatments of the diversity of perspectives associated with these two methodologies are encouraged to examine other chapters in this volume (e.g., Schoonenboom, in press; Stake and Visse, in press) as well as the extensive literature available about mixed methods research and about case study research.

Mixed methods research defined

Mixed methods research is an approach to educational inquiry that combines two research components: one qualitative method (textual data) and one quantitative method (numeric data) within a single study such that the two types of data and analyses are brought together to respond to the study's aims (Johnson et al., 2007). In a mixed methods study, using one methodological approach simply will not answer all parts of the questions posed (Tashakkori et al., 2021). By carefully designing the qualitative and quantitative components of the study, investigators are able to intentionally integrate the various methods so that results maximize the response to research questions (Fetters and Freshwater, 2015). Integration occurs when researchers bring the different study components together into conversation with each other (such as by comparing qualitative themes to quantitative statistical results). Integration can be accomplished by connecting or merging the different components into a new whole so that new insights are generated from the combination (Creswell and Plano Clark, 2018).

Although education scholars agree that achieving integration is central to mixed methods research (Creswell and Plano Clark, 2018; Tashakkori et al., 2021), they often bring different assumptions about the nature of the social world and how they are able to learn about it through research. Several distinct sets of philosophical assumptions are associated with mixed methods research (Shannon-Baker, 2016). Educational researchers using mixed methods research often draw from ideas aligned with pragmatism (Johnson and Onwuegbuzie, 2004; Morgan, 2014), dialectical pluralism (Greene, 2007; Johnson, 2017), critical realism (Maxwell and Mittapalli, 2010), and transformative perspectives (Mertens, 2012). These different perspectives describe researchers' mental models for how knowledge is generated when combining different approaches and therefore shape what is being mixed and for what reasons in mixed methods studies.

In combination with philosophical assumptions, educational researchers invoke a mixed methods approach to their inquiries for several reasons (Greene et al., 1989). A widely cited rationale for using mixed methods is triangulation, where researchers directly compare the findings from the quantitative portion of a study (e.g., survey results) and the qualitative portion of a study (e.g., focus group findings). Triangulation provides assurance that the description of the phenomenon is stable across methodological components. Another rationale for using mixed methods is complementarity, which aims to produce elaborated or clarified results by using the strengths of the different methods to examine different facets of the phenomenon of interest. Complementarity allows the qualitative and quantitative components to each illuminate unique aspects of the examined phenomenon so that, when combined, they generate expanded understandings. A third rationale for using mixed methods is initiation, which intentionally seeks to locate areas where cross-method agreement is not present, resulting in what may appear to be, at first glance, contradictory findings. Initiation requires researchers to dig deeper into the analyses and probe additional perspectives to integrate the findings from the quantitative and qualitative parts into a meaningful interpretation. In short, reasons for invoking a mixed methods approach to research vary, but always aim to enhance knowledge of complex and multifaceted issues such as those found in education. Further discussion of the nuances in how mixed methods research is defined and the importance of different rationales are found elsewhere (for more on this, see Hesse-Biber and Johnson, 2015).

Case study research defined

Case study research is a predominantly qualitative approach to educational inquiry that is dedicated to developing in-depth understanding of one or more case(s) that represent bounded systems (Creswell and Poth, 2018; Yin, 2018). Case study researchers aim to understand how a phenomenon of interest (e.g., an activity, program, or event) exists in particular time(s) and place(s) (e.g., a classroom over the course of a year) (Creswell and Poth, 2018; Yin, 2018).

As with mixed methods research, researchers who work from a variety of philosophical positions are drawn to use case study research to address their aims and research questions. In education, commonly discussed perspectives associated with case study research include postpositivism, constructivism, and critical realism (Harvey, 2009; Schwandt and Gates, 2018; Yazan, 2015). Each of these perspectives gives a different emphasis to the application of case study research in education by placing importance on objectively describing a case, interpreting the meaning of the case, or identifying causal mechanisms acting within the case. Thus, the researcher's perspective informs how and why researchers select cases and the kinds of knowledge derived from the study of the cases.

Keeping these variations in mind, researchers using case study often invoke this approach for several reasons. First, case studies are selected for their flexibility of methods. Researchers employing a case study design may collect qualitative data from observations, interviews, and artifacts; however quantitative data, such as from surveys or test scores, are also well-suited for use in a case study (Luck et al., 2006; Yin, 2018). Moreover, researchers also have flexibility when choosing whether to investigate single or multiple cases (Merriam, 1998; Stake, 1995; Yin, 2018). Another reason for choosing a case study design is the ability to focus both on the phenomenon under investigation and on how it operates within the specific context of the case. A case study approach blurs the boundaries between phenomenon and context, allowing researchers to access understandings of the ways the context and phenomenon may interact with one another (Creswell and Poth, 2018; Merriam, 1998; Yin, 2018). A final reason for choosing case study methodology relates to the multiple ways cases themselves can be defined within a study. While cases can be defined by geographical location, they can also be conceptualized more abstractly (Ragin, 1992; Yin, 2018). As an example, a case can be concrete, such as a student or a school, but a case could also be more abstract, such as an incident or a group of schools deemed alike in some theoretical manner. Further discussion of other potential definitions of a case and the importance of describing what constitutes a case in a study can be found elsewhere (for more on this, see Ragin, 1992).

Frameworks for combining mixed methods and case study research

Although mixed methods research and case study can be defined as stand-alone and distinct inquiry approaches, there are many examples where researchers have combined the two in their studies to address their questions of interest. Researchers across disciplines including education are drawn to the ability of mixed methods approaches to provide comprehensive insights and the ability of case study approaches to provide rich descriptions of complex systems (Guetterman and Fetters, 2018). These two approaches can work well together, but the combinations can be challenging to plan, understand, and evaluate because of all the different methods that may be employed and the resulting variety of methodological considerations necessary. Here we highlight three frameworks useful for understanding different combinations found within education: (a) examining cases within a mixed methods study, (b) mixing methods within a case study, and (c) intersecting the two approaches to form a mixed methods case study. The frameworks differ in terms of the relative emphasis placed on the mixed methods approach and the case study approach for addressing the study's purpose. These differences are depicted in Fig. 1 and described in the following sections.

Examining cases within a mixed methods study

When researchers conduct and report mixed methods research studies, by definition these studies include both a quantitative component and a qualitative component (Creswell and Plano Clark, 2018). Therefore, one way that researchers combine mixed methods and case study research is to use a case study approach for the qualitative component of a mixed methods study. There are three different times when the qualitative case study component can occur in relation to the quantitative component: it can occur first and inform the quantitative component, it can occur at the same time as the quantitative component for comparison, or it can occur after the quantitative component to explain aspects of the quantitative results. In each of these possibilities, the case study component provides in-depth information about cases to complement the quantitative aspects of the mixed methods studies.

As depicted in diagram (A) of Fig. 1, educational applications that correspond to this framework are described as mixed methods studies where the researchers use a case study approach for the qualitative component of the study's mixed methods design. Yin (2018) referred to applications such as this as studies where "the larger (mixed methods) study encompasses the case study" (p. 235). More recently, mixed methods scholars Guetterman and Fetters (2018) similarly described this framework as having a "parent" mixed methods study that includes a "nested" case study (p. 901). As these descriptions convey, this framework emphasizes the use of mixed methods as the guiding design for the study with the use of case study for the qualitative component in support of the overall mixed methods study goals.

A Examining Cases Within a Mixed Methods Study

B Mixing Methods Within a Case Study

C Intersecting the Two Approaches to Form a Mixed Methods Case Study

Fig. 1 Three different frameworks for combining mixed methods and case study research, (A) examining cases within a mixed methods study, (B) mixing methods within a case study, (C) intersecting the two approaches within a mixed methods case study.

Ivankova and Stick's (2007) mixed methods study of persistence in an online doctoral program is an example of a study that illustrates examining cases within a mixed methods study. Working from a pragmatic perspective, the authors used a mixed methods design that started with quantitative data collection and statistical analyses to identify internal and external factors that differentiated four groups of students defined by their level of persistence. Next, they conducted a qualitative multiple case study that examined the experiences of four typical students (one from each group) to explain the role of the identified factors. As such, this study used a sequential mixed methods design that incorporated a case study approach for the second, qualitative phase to provide an expanded understanding about the initial quantitative results.

Mixing methods within a case study

As depicted in diagram (B) of Fig. 1, the second framework for conceptualizing combinations of mixed methods and case study switches the emphasis between the two approaches from the previous framework. In this framework, the case study approach is the guiding methodology for the study and the researcher chooses to mix quantitative and qualitative methods to meet the case study objectives. Yin (2018) noted that researchers could use both quantitative and qualitative evidence to better describe the case(s) investigated (p. 63). Similarly, Guetterman and Fetters (2018) described this framework as having a "parent" case study that includes a "nested" mixed methods design (p. 901).

For many who are interested in the use of case study in education, mixing methods within a case study is simply an example of doing good case study research (Byrne, 2009; Yin, 2018). Australian scholars Luck et al. (2006) argued that case study was particularly well suited to provide a framework for combining quantitative and qualitative methods. They described the case study

methodology as being able to provide a bridge between the different methods. For example, scholars might use different methods (e.g., interviews, document analysis, surveys, and observations) to examine different stakeholders' experiences (e.g., administrators, teachers, students, and parents) and contexts of interest (e.g., demographics, performance, trends over time) to form in-depth descriptions of the cases. Such studies can be considered as case study research, but with a close examination of the details, it is apparent that the researchers combined both qualitative and quantitative data to enhance understanding of cases of interest.

Auslander et al. (2020) is an example of a study that illustrates mixing methods within a case study. The researchers designed a holistic, single-case study to examine teacher candidates' preparation for a newly mandated teacher assessment within the context of a university mathematics methods course. Data collected from all participants ($N = 51$) included pre- and post-course belief questionnaires containing open-ended qualitative and close-ended quantitative items related to pedagogy and teaching efficacy. Additionally, a portion ($n = 6$) of the participants were interviewed. Results of the quantitative and qualitative analysis were reported separately. No shift in teacher candidates' beliefs were detected in the quantitative analysis; the robust qualitative analysis described four themes that emerged from the interviews and open-ended questionnaire data. This study represents this framework since the emphasis was on describing the case with little attention given to mixed methods aspects such as integration of the different data and results.

Intersecting the two approaches to form a mixed methods case study

A third framework used to conceptualize the combination of mixed methods and case study research comes from the concept of intersecting. *Intersecting* is the intentional combination of the assumptions, designs, and methods of two distinct research approaches to form a hybrid approach to research (Plano Clark and Ivankova, 2016). From this perspective, researchers can intentionally combine the assumptions, designs, and methods of mixed methods research with the assumptions, designs, and methods of case study research to form a hybrid, mixed methods case study approach (Plano Clark et al., 2018; Walton et al., 2020). This conceptualization of mixed methods case study as the intersection of mixed methods research and case study research is depicted in diagram (C) of Fig. 1.

Building on these ideas, *mixed methods case study research* can be defined as an approach to educational inquiry that mindfully combines elements of each approach in ways that integrate the qualitative and quantitative findings to generate enhanced knowledge of the case(s) under investigation (Guetterman and Fetters, 2018; Plano Clark et al., 2018). As a hybrid approach, mixed methods case study can be considered as a complex research application with its own variants, procedures, and quality considerations drawing upon the many options and variations available for mixed methods research and case study research (Creswell and Plano Clark, 2018). In contrast to the previous two frameworks that gave a clear priority to one of the approaches (either mixed methods research or case study research) for providing the guiding methodology to a study's design, the intersecting perspective conceptualizes the two methodologies as equal partners in a study's design, which is depicted by the two larger overlapping circles in Fig. 1C, with negotiation between the different assumptions, designs, and methods.

Walton's (2014) mixed methods case study of a collaborative partnership to support STEM education is an example of a hybrid approach that emphasized both mixed methods and case study equally in the study design. The researcher's pragmatic approach pressed upon her the need for both mixed methods and case study thinking when approaching the examination of the partnership's structure and activities. The theoretical underpinnings of the study suggested the usefulness of a dual focus on the level of collaboration in the partnership and on partners' perceptions of the application of research-based collaboration practices. This theoretical framework led the researcher to a concurrent mixed methods approach to the study and drove the integration of findings from a quantitative measure of collaboration with findings from qualitative data gained from partner interviews. At the same time, the study was framed within a partnership that was deemed unique based upon its leadership structure. The uniqueness of the case led naturally to a case study approach that aimed to provide a rich description of the partnership and insight into the impacts of the leadership structure. The case description and interpretation, a dialogue between the broad view of collaboration and the fine-grained partner perspectives of partnership practices, had as its foundations the mixed methods integration strategies suggested by the study's theoretical framework.

Applying the three frameworks

Each of the three described frameworks provides a slightly different way of thinking about how case study research can be combined with mixed methods research in educational studies. They each tend to draw on different literature, use different terminology, and have study purposes and questions that emphasize different aspects of the studies. However, they also have many commonalities, such as the study of a case or cases, the use of both quantitative and qualitative methods, and the intention to learn from complex, real-world situations. Each of these frameworks is present and useful within education so it is helpful for reviewers and consumers to be aware of the different perspectives they may encounter when reading published reports of studies that combined mixed methods and case study research. Investigators planning studies will likely find that they are more drawn to one of these frameworks depending on how the combined approaches can best address the particular question of interest. As such, readers are encouraged not to think of these three frameworks as either-or types and certainly not to value one over others. Instead, each framework highlights a different way that these two useful approaches can be used together in research studies to advance understanding about important educational issues and systems.

Key decisions when combining mixed methods and case study research

All researchers, regardless of the types of studies they undertake, should plan those studies with careful consideration of issues such as their philosophical perspective and what research design best fits the research questions they seek to answer. Because of its utility and flexibility, a combined mixed methods case study approach is suitable for researchers who are associated with a variety of the philosophical perspectives discussed previously, including pragmatism, postpositivism, dialectical pluralism, critical realism, and transformative perspectives. For all of these perspectives, the mixed methods case study approach offers the ability to combine quantitative and qualitative information about cases to develop comprehensive and nuanced conclusions in response to specific research questions about complex phenomenon occurring within bounded systems.

Once researchers have chosen to use mixed methods case study to investigate research problems, they face decisions specific to combining case study and mixed methods approaches in a study. These decisions influence the orientation, depth, and breadth of a study's findings. Therefore, consumers of research should have a basic familiarity with key decision points as they read reports of mixed methods case study research for information to guide practice and policy. These decisions relate to key aspects of case study design, mixed methods design, and the use of integration strategies to enhance the understanding of cases.

Since the various decision points researchers navigate in conducting mixed methods case studies are best illustrated in the context of applied research, the sections that follow will rely on two hypothetical exemplar studies. In each of the hypothetical studies, the researcher aims to understand the phenomenon of challenges associated with online teaching in primary grades, however the researchers in the two studies each make key decisions that result in very different study designs and findings.

In the first hypothetical study, which we refer to as the "online bilingual school study," the researcher investigated instructional challenges faced by a fully online school using a dual-language immersion approach. This researcher collected data concurrently from teacher interviews and a survey administered in the same two-week period in which interviews were conducted. The study culminated in a case report that wove together individual (interview) and school-level (survey) challenges to online instruction in order to create a holistic picture of challenges within this school.

In the second hypothetical study, referred to herein as the "regional school study," the researcher conducted a study that also aimed to understand challenges in online teaching, but this researcher chose to conduct a multiple case study to examine a sample of schools taken from one geographic region. This researcher employed a survey to identify several schools that represented various demographic features and student outcomes and then used administrator interviews and student performance data from online courses at the selected schools to create reports for each case. These case reports depicted relationships between school-level resources (from the survey and interviews), school demographics (from the survey), and students' learning outcomes (from student performance data). The individual cases were then compared with the aim of understanding the differences in learning outcomes between schools with varying resources and demographic features.

The two hypothetical studies serve as a representation of just two of almost limitless ways in which mixed methods and case study can be combined. They illustrate the ways in which studies with similar purposes, both utilizing mixed methods case study approaches, can diverge in the scope and focus of their findings based on the researchers' choices. Building on the concepts already discussed, the following sections use the two hypothetical studies to illuminate three key sets of decisions regarding: (a) case study design and case selection, (b) mixed methods design and timing, and (c) the use of integration strategies to enhance case interpretation.

Case study design and case selection

The first key decisions we highlight for mixed methods case study approaches relate to the case study design and case selection. A researcher's choice of case study design in terms of the number of cases chosen for study (single case study or multiple case study) is a decision guided by the intent of the study. [Table 1](#) provides an overview of possible rationales for case selection in both single and multiple case studies along with the study purposes that guided case selection in each design. An examination of the two hypothetical studies reveals nuanced differences in study purposes and case selection rationales that led to the two different designs employed.

The researcher in the bilingual school study aimed to understand the challenges associated with online teaching in a case of particular interest. The researcher chose the case because of the unique setting of the case (i.e., online content being delivered in more than one language). The bilingual nature of instruction was a unique feature of this school that was intrinsically interesting to the researcher, and this study therefore aligns with [Stake's \(1995\)](#) conceptualization of an intrinsic case study. According to [Stake \(1995\)](#), an intrinsic case study is one that examines a single case that is interesting in itself, where the study is conducted in order to understand something about the particular case. Intrinsic case studies do not aim to create knowledge that can be applied across a variety of contexts.

The regional school study differs in the scope of its aims. Here, the researcher's purpose was to understand how learning outcomes in online courses are related to school context features. The purpose of this study was instrumental, meaning that the cases were studied in order to understand a phenomenon that transcended the individual cases ([Stake, 1995](#)). In this study, the interaction between school context and learning outcomes was the focus and, while the findings may not be broadly generalizable because of the small sample size of cases, other schools with similar contextual features might be guided by the study's findings.

Table 1 Case study designs: Case selection rationales and study purposes.

<i>Case type</i>	<i>Purpose of the study</i>	<i>Case selection process</i>
Single case – Intrinsic	To illuminate a single case as a particularly interesting instance of a phenomenon	Interest in the case as an individual situation may precede the study design; single cases may be critical, unusual, common, revelatory, or longitudinal
Single case – Instrumental	To explore a phenomenon within a bounded case to understand something beyond the case itself	Select a single case that is: critical, unusual, common, revelatory, or longitudinal; this decision relates to which cases provide the best opportunity to answer the research question
Multiple case – Collective (literal replication)	To examine a phenomenon in several cases that are similar to one another on a key dimension	After compiling a set of cases that meet the criteria for study inclusion, cases are reviewed for varying secondary characteristics. Cases are selected to broaden the opportunity to learn about the phenomenon of interest in its many manifestations and based on wider variety
Multiple case – Comparative (theoretical replication)	To compare and contrast cases based on their membership in distinct groups to determine how the phenomenon of interest exists in each of these groups	Cases from each group are selected to address rival explanations; for example, stratified or matched sampling across groups helps to control for other case features that may impact the comparison

Case study design ideas from [Stake \(1995\)](#) and [Yin \(2018\)](#).

The hypothetical studies highlight the role of case selection as a key decision point for researchers. The case study design, which includes the number and identity of cases selected, is closely tied to the purpose of the study in question. Determining the number of cases and which to select may be a process that interacts iteratively with formulating research purposes and questions. Researchers should first consider whether examining activities within a specific case or cases will provide insight into the research questions posed.

The study's purposes and research questions may call for multiple cases to be investigated and compared in order to understand differences across cases chosen for their varying contextual features. In some studies, the case selection process may represent a unique phase of the study and rely on quantitative methods to determine cases' eligibility for inclusion. For example, educational effectiveness researchers often group schools into comparative sets by their student outcomes while quantitatively controlling for demographic school features. These researchers use an initial quantitative phase to classify schools into sets for comparison, then make final case selections from these sets of schools (e.g., [Teddlie et al., 1985](#)).

The hypothetical examples and the example of educational effectiveness studies highlight some of the challenges associated with case study design, which include determining the number and selection of cases. Researchers conducting intrinsic case studies must provide a rationale for the in-depth investigation of the particular case ([Yin, 2018](#)) and must carefully determine the unit of analysis (e.g., a school, one class within a school, or a single grade level across several schools in a region) that will be investigated to address the study's aims ([Ishak and Bakar, 2014](#)). Likewise, researchers conducting instrumental case studies need to determine which cases will best provide information about the phenomenon that is the focus of the study, with the recognition that such decisions may necessitate a first phase of robust analysis of cases to inform well-reasoned case selection.

Mixed methods design and timing

A researcher choosing to use a mixed methods approach to a case study is faced with an array of possibilities for collecting, analyzing, and integrating quantitative and qualitative data and findings. Researchers' decisions about how and when to collect various types of data are driven by their purposes or rationales for incorporating multiple forms of data into their studies. [Greene et al. \(1989\)](#), [Bryman \(2006\)](#), and others have advanced sets of rationales for using mixed methods that include sampling or case selection, triangulation, complementarity, explanation, and instrument development. The researcher's rationale for collecting multiple types of data may be explicitly stated in the case study report. However, more often the rationale is implicit, and the reader of research studies is left to infer the rationale based upon the study's purposes and designs ([Heyvaert et al., 2013](#)).

Several typologies have been advanced to describe study designs where qualitative and quantitative methods are combined in a single study (e.g., [Creswell and Plano Clark, 2018](#); [Guest, 2013](#); [Tashakkori et al., 2021](#)). Researchers frequently use language that reflects the timing of data collection and analysis as well as the priority of qualitative and quantitative methods and data to describe their mixed methods designs. [Morse \(1991\)](#) advanced a notation system that relies on the abbreviated terms "quan" and "qual" to refer to quantitative or qualitative data, capitalizes one or the other term to indicate relative priority (e.g., QUAL to describe a study with a qualitative priority or QUAN to describe a study with a quantitative priority), and uses arrows (→) and plus symbols (+) to depict the timing and flow of data collection and analysis. [Creswell and Plano Clark \(2018\)](#) advanced a framework of three core

Table 2 Mixed methods designs: Timing and notation considerations.

Core mixed methods design	Timing of data collection and analysis	Possibilities for notation
Convergent	Qualitative and quantitative data are collected and analyzed simultaneously (or concurrently) to develop a comprehensive picture	(a) QUAL + quan (b) qual + QUAN (c) QUAL + QUAN
Explanatory sequential	Quantitative data is collected and analyzed in a first phase; first phase findings are used to inform a second phase in which qualitative data is collected and analyzed to explain quantitative findings	(a) QUAN → qual (b) quan → QUAL
Exploratory sequential	Qualitative data is collected and analyzed in a first phase; first phase findings are used to explore an issue and inform the design of a quantitative phase (e.g., a survey instrument) used to determine how the first phase findings relate to a different or larger population	(a) QUAL → quan (b) qual → QUAN

Mixed methods design ideas from [Creswell and Plano Clark \(2018\)](#) and [Morse \(1991\)](#).

mixed methods designs that focus on the timing of data collection and analysis: convergent design (simultaneous collection of qualitative and quantitative data), explanatory sequential design (a quantitative phase followed by a qualitative phase), and exploratory sequential design (a qualitative phase followed by a quantitative phase). [Table 2](#) presents these core designs and provides examples of how they may be described in literature using [Morse's \(1991\)](#) notation system.

Examining the two hypothetical studies through the lenses of mixed methods design and rationale reveals key decisions addressed by each researcher in terms of the mixed methods designs and timing employed. In the bilingual school study, the researcher collected and analyzed both interview and survey data simultaneously, but relied primarily on interview findings in the production of the case report, using quantitative survey findings to lend further insight into the qualitative findings. The researcher's rationale for using multiple data sources was the complementarity of the interview and survey constructs and the desire to use the two datasets to create a more complete picture of the challenges of online instruction in the bilingual school. Using [Morse's \(1991\)](#) notation system, the timing and mixed methods design of the study could be described as QUAL + quan.

In contrast, the regional school study used a sequential design with two distinct phases. First, the researcher defined four sets of context and outcomes criteria based on a guiding theoretical framework for the study, and employed a quantitative survey to select four school cases from the region, each of which met one of the criteria sets. In a second phase of the study, the researcher collected qualitative (interview) and quantitative (student performance) data at each of the selected schools, and generated a case report for each. The challenges to online instruction in each setting were then compared using the initial theoretical framework as a guide. The researcher's rationale for using multiple types of data included sampling (to inform the case selection) and complementarity (to gather complementary data to inform a broader and more nuanced understanding of the challenges to online instruction).

The design of the regional school study is not as easily described by any one of [Creswell and Plano Clark's \(2018\)](#) three core designs or [Morse's \(1991\)](#) notation system. From a timing perspective, the study utilized an initial quantitative phase followed by a second, convergent phase in which both quantitative and qualitative data were collected and analyzed simultaneously, a design that might be described using [Morse's \(1991\)](#) notation system as QUAN → [QUAL + QUAN]. The latter example points to the challenges associated with applying existing typologies to mixed methods case study designs due to the many options available for researchers for the key decisions.

The typologies and notation system discussed here are examples of commonly used frameworks for discussing mixed methods designs and are not exhaustive. While the savvy consumer of research may wish to become familiar with these conventions, he or she should remain aware of their limitations in depicting mixed methods case studies. As [Walton et al. \(2020\)](#) noted, conventions of timing and priority may fall short in attempts to describe mixed methods case studies. Likewise, [Creswell and Plano Clark \(2018\)](#) acknowledge these challenges, noting that "complex designs" (p. 102) that intersect mixed methods designs with other research approaches such as case study may not be fully described by any one of the core designs.

The use of integration strategies to enhance case interpretation

The third type of decision of interest in mixed methods case study are decisions about integration and interpretation. The use of mixed methods integration strategies to create linkages between qualitative and quantitative methods, datasets, and findings is a defining feature of mixed methods research (e.g., [Onwuegbuzie and Johnson, 2006](#); [Fetters, 2020](#)). In fact, methodologists have proposed that it is the use of such integration strategies that differentiates a mixed methods study from a study that, while it may collect multiple forms of data, holds data and findings in parallel without drawing relationships between them (e.g., [Plano Clark et al., 2018](#)). Mixed methods integration strategies drive data analysis procedures and the representation and interpretation of findings, and are typically closely linked to a study's purposes and to the mixed methods design employed ([Creswell and Plano Clark, 2018](#)).

There are numerous points within a study where qualitative and quantitative research approaches and procedures can interface, encompassing all phases of a study from the posing of research questions to the drawing of inferences from a study's findings (Fetters et al., 2013). Mixed methods integration strategies include text-based or tabular side-by-side comparisons of qualitative and quantitative data findings (Guetterman et al., 2015); the transformation of qualitative data to quantitative data (quantitizing) or vice versa (qualitizing) (Nzabonimpa, 2018); and using the findings of one strand of a study to inform a second, sequential strand (e.g., using qualitative data to identify important context features of sites to inform case selection) (Creswell and Plano Clark, 2018). Regardless of the strategy used, the ultimate goal of the integration strategies is to bring quantitative and qualitative findings into conversation with one another in order to provide new or more holistic insights into the issues under investigation.

The researchers in the hypothetical studies made various decisions to create conversations between the quantitative and qualitative databases and to make enhanced interpretations about the cases under study. In the bilingual school study, for example, the researcher compared and contrasted themes from teacher interviews with related findings from the survey constructs, presenting the findings from this process in a table where quantitative findings from a survey construct (e.g., ease of access to technology support) were displayed beside interview quotes reflecting either common or divergent findings. This joint display of combined findings served as a guide for case interpretation in an in-depth case report that outlined challenges to online teaching in this setting.

In the regional school study, the researcher had the opportunity to employ various integration strategies throughout the study. This researcher, for example, quantitized data from administrator interviews by counting codes for three constructs related to the theme of resource scarcity in the interview findings. The researcher then compared the relative frequency of these constructs within the interview data from each site to student outcome data in order to better understand how perceptions of resource scarcity related to student outcomes in online learning. The regional school study researcher also used findings from the first, quantitative, phase of the study in which demographic data for all schools in the region were collected as a contextual backdrop for the interpretation of individual cases.

Applying the key decisions

The decisions described in this section ultimately determine the focus and breadth of a study's findings and how these findings can be used. In order to understand the impact of these decisions on the use and further applications of a study's conclusions, consumers of research should analyze reports of research to understand how and why researchers combined these approaches and made decisions regarding case study and mixed methods elements of the study. Mixed methods case study researchers should therefore carefully consider decisions regarding how case study and mixed methods approaches are combined and should articulate their rationales for these choices in their study reports.

Applications of mixed methods case study in education

To illustrate the key decisions and considerations that have been discussed, in this section we present a brief examination of three existing education studies employing mixed methods case study. We have intentionally included different contexts and design elements to pique readers' interest as they consider the wide variety of possibilities available for designing their own mixed methods case study investigations.

In our first example, Duffin and Perry's (2019) mixed methods case study used a convergent design in which all data were collected simultaneously. These researchers aimed to understand how a Place-Based Ecology Education (PBEE) community, an intrinsically interesting case, contributed to changes in teacher practice. The PBEE community was an example of a unique collaborative approach to providing coordinated, impactful professional development to primary and secondary teachers situated in schools in the northeastern portion of the US. The researchers collected data concurrently using surveys and evaluator notes. Surveys generated both quantitative (Likert-scale numeric responses) and qualitative (open responses in participants' own words) data; additional qualitative data came from evaluators' notes. The researchers analyzed the quantitative data to determine whether changes in practice were statistically significant (t-tests) and to gauge the varying impact of different amounts of professional development (regression and cluster analysis). They separately analyzed the qualitative data to identify themes related to implementation and support needs. All results were then brought together for additional integrative analysis by displaying qualitative themes alongside quantitative professional development dosages and the stages of development reported. By merging the two types of data to produce a more complete understanding of the case, the researchers could "discover insights into best practices for PBEE professional development" (Duffin and Perry, 2019, p. 7).

Our second exemplar study is Wise et al.'s (2012) mixed methods case study, which aimed to capture individual students' experiences during asynchronous online interactions in an undergraduate course in Canada. Multiple cases were chosen to better understand the range of practices exhibited by students in online discussion boards. To account for the variety of activity, three student cases were selected based on a preliminary analysis indicating that these cases exhibited extreme online behaviors (e.g., in terms of frequency of visits to discussion board, length of session, frequency of self-reviews). The researchers collected quantitative and qualitative data concurrently as students interacted on an online discussion board. Data included quantitative log-file data measuring engagement time, determined reading versus skimming, and situated posts in timelines, while content of the posts served as the

Table 3 Example of a side-by-side joint display used to merge results.

Theme	Context 1 schools (schools in poorer, less-educated communities)	Context 2 schools (schools in wealthier, better-educated communities)
Assignment of students to classes	Heterogenous: Mix of all abilities in each classroom; to spread out the level of need; all types of need present in each classroom	Homogeneous: Students assigned to classes by ability (high with high, low with low); to allow teachers to modify instruction for one type of need; assignment of aides to support lowest achieving group
Assessment on math progress	Screening tests: 3 times a year; plus weekly monitoring (computer)	Screening tests: 2–3 times per year
Team meetings to review data	Weekly (teachers only)	2–3 times per year (teachers only or full diagnostic team)
Math supports for “strugglers” (without IEPs; Tier 2)	Provided by teacher	Provided by teacher, aides, and intervention specialists
Support for students with diagnosed math disabilities (Tier 3)	30 min per day with intervention specialist	Aide support during math class and 30 min per day with intervention specialist

Modified from Foote (2019, p. 186). Context 1 Schools and Context 2 Schools (seen in the second and third columns of this table) were two of the theoretical groups of school cases generated using quantitative methods (cluster analysis). The themes related to the operations of the schools; these were informed by the best-practices literature and qualitative differences present when comparing the two context types. This joint display allows readers to directly compare how operations in each context varied by theme. Ultimately, while schools in both contexts attempted to employ recommended best practices, needs and resources associated with each type of case resulted in different operations.

qualitative dataset related to the study’s theoretical framework. Integrating findings by creating joint displays of qualitative and quantitative findings allowed the investigators to generate narratives richly characterizing each student case and offering nuanced insights regarding conceptualizations of student online behaviors.

Our final example is Foote’s (2019) mixed methods case study aimed at understanding how elementary mathematics supports exist in different school contexts in the US. Using a sequential design, the researcher started by gathering quantitative data and used cluster analysis to generate groups of schools based on demographic features, resulting in seven unique sets of schools. Two of these groups of schools were selected for comparison based on maximum differences in contexts, and two individual school cases were selected from each selected group (for a total of four cases for study). Qualitative data were gathered for each case through interviews and classroom observations, then analyzed using thematic coding. All data were brought together in a comparative table (see Table 3) that displayed similarities and differences in schools’ methods for supporting mathematics learning. Results indicated that supports for students who struggled in mathematics varied by school context, providing a more nuanced view of mathematics supports in elementary schools.

As this examination of several mixed methods case studies illustrates, researchers using this combined mixed methods case study approach have the opportunity to integrate qualitative and quantitative methods to produce robust inferences related to single or multiple cases. In each educational example described, there is evidence that the researchers conceptualized how case study and mixed methods research elements could be fruitfully placed within an overarching design to respond to research aims and generate important insights about complex educational situations.

Future directions

Mixed methods case study has emerged as a valuable methodological option for educational researchers wanting to generate practical knowledge about what is happening within educational systems. This combined research approach has the potential to highlight examples of promising educational practices and suggests novel approaches to investigating important educational research questions and the local results of regional, national, and global policies. As the methodological thinking regarding mixed methods case study evolves, new ideas emerge for ways to conceptualize mixed methods case studies. In addition, the increasing prevalence of global issues impacting and interacting with the field of education suggest new areas of inquiry for researchers, new ways that researchers can conceptualize and bound cases for investigation, and the novel use of data and data analysis strategies within case studies.

As methodological understandings of mixed methods case study advance, new ways to conceptualize and discuss mixed methods case study are emerging (e.g., Guetterman and Fetters, 2018; Plano Clark et al., 2018). Due to the emphasis on description and the small number of cases examined in most studies, case study has long been perceived as a qualitative methodology with extremely limited potential for generalizability and has therefore been dismissed by some researchers seeking to influence public policy or generalize a study’s conclusions across an array of settings (Tsang, 2014). Mixed methods approaches to case study that creatively incorporate multiple sources of both qualitative and quantitative data may expand the scope of study findings beyond those traditionally associated with case study research, suggesting the potential to

legitimize case study among researchers and public policy makers. Similarly, due to many scholars' predilection for quantitative research, mixed methods research has long been perceived as an approach that undervalues qualitative research and employs weak qualitative methods (Giddings, 2006). Case study approaches to mixed methods research that creatively apply in-depth qualitative case study methods along with robust quantitative methods and integration strategies can enrich the findings generated by mixed methods research and advance the contribution of both mixed methods and case study research in the field of education.

Trends toward increasing globalization create broad-scale background conditions, or meta-contexts, in which national, regional and local contexts are nested. Meta-contexts such as that of the COVID-19 pandemic may shift researchers' thinking about topics relevant to educational research, the data sources that can be used in mixed methods case studies, and how systems are bounded and cases defined. Questions regarding the role of education in areas such as climate change and social injustice, and questions about how school policies affect public health may be addressed by leveraging the strengths of combined case study and mixed methods approaches. These meta-contexts, along with the increasing application of systems thinking in educational research (e.g., Mette and Riegel, 2018; Verhoeff et al., 2018), may also lead to new considerations of how cases are bounded and may present opportunities for multiple case study researchers to conceive of new ways to understand and describe case interdependence.

Research findings over the past several decades have highlighted the fact that educational outcomes are influenced by a number of contextual features (e.g., Chapman et al., 2012), suggesting that educational practitioners and policy makers should be especially mindful of the criteria and techniques they use to select cases for examination. The use of rigorous mixed methods approaches in case studies may result in the application of sophisticated methods such as cluster analysis (Foote, 2019) that have implications for the selection of and interpretation of cases. In addition, as large and less traditional data sets emerge, mixed methods case study researchers may grapple with whether or how to incorporate, for example, social media and biosocial data, into their studies.

Concluding comments

Mixed methods case study provides an agile framework with which to gain a deep understanding of educational issues and problems within a variety of contexts. The answer to the question "what happened here?" can be used to inform educators' practices, policy makers' decisions, and other researchers' research agendas. We conclude with recommendations for those conducting mixed methods case studies and those seeking to use the findings of these studies for practical purposes.

The understanding of the ways that case study and mixed methods approaches can be combined and the ways that the resulting studies can be described continues to evolve. Those interested in mixed methods case studies should therefore approach the conduct of and interpretation of such studies not with a rigid set of criteria with which to assess findings, but rather with an understanding of the considerations unique to the combined approach. Investigators creating research reports are encouraged to articulate clearly their studies' purposes, their rationales for the bounding and selection of cases, their choices of data sources, the timing of the quantitative and qualitative methods and the ways that they are combined, and their purposes for combining methods. Furthermore, producers of research should carefully consider how integration strategies can enhance their case interpretations and carefully frame their case reports in ways that allow consumers of research to assess the applicability of the findings to their own practices.

We recommend that consumers of research – graduate students, educators, policy makers, and others – carefully examine reports of mixed methods case studies for evidence of researchers' decisions about the points mentioned. Situating this information within the context of their own goals for reading the report may provide important information regarding the applicability of studies' findings to readers' specific needs. The following questions are provided as a guide for interested readers of mixed methods case study reports:

- What is the phenomenon being investigated in the study?
- Why and how were the cases chosen and how do they relate to the study's goals?
- What is the unit of study and how does investigating this unit answer the research questions posed?
- What is the purpose and timing of collecting and analyzing multiple forms of data?
- How do the different forms of data relate to the study's goals?
- What new insight is provided by the integration of the qualitative and quantitative data and methods?
- How does the researcher suggest that the findings of this study be used, and does the study's design warrant this use?

The potential of mixed methods case studies to provide comprehensive understandings of complex situations can be leveraged by both producers of and consumers of research to advance knowledge in the field of education, inform public policy, gain deep understanding of the implications of contextual factors for educational issues, and identify promising educational practices. As we grapple with changing meta-contexts and new areas of inquiry in education, this combined approach may increasingly appeal to researchers who seek to provide in-depth understandings of these complex situations.

Introduction

Researchers are gradually acknowledging the potential for methodological innovation that can be achieved through combining multiple methods within single research studies by utilizing mixed methods research (MMR) approaches. In recognition of this increasing popularity, and to address concerns regarding the uncritical adoption of MMR within research designs (Sale et al., 2002) there is a need for in-depth philosophical and methodological discussion with regards to how multiple methods can be combined on both a paradigmatic and practical level within research studies, as well as practical examples of these approaches being adopted successfully. Increasingly, methodologists are providing guidelines on how qualitative research traditions with established histories such as grounded theory (Johnson et al., 2010), performative methods (Schoonenboom, 2019), narrative (Waller et al., 2020) and phenomenology (Mayoh and Onwuegbuzie, 2015) can be sympathetically combined with quantitative methods to provide such methodological innovation.

In line with this movement and the recognition of the ongoing discussion that the phenomenological method works particularly well as a component of MMR designs (Mayoh and Onwuegbuzie, 2015), the purpose of the following chapter is to provide both a philosophical and practical discussion regarding the intersection between phenomenology and methods grounded in post-positivism within a single study, and showcase two practical examples of mixed methods research that incorporated phenomenology in a philosophically sensitive manner. In doing so, we present an overview of the ongoing conceptualization of Mixed Methods Phenomenological Research (MMPR) and help provide a framework for the use of phenomenology as a component within MMR. To provide a more comprehensive discussion, we deliberate different forms of phenomenological methodologies, namely descriptive (eidetic) and interpretive (hermeneutic), and the associated philosophical and methodological assumptions and compatibility with alternative methods. This engagement with the philosophy of mixing methods has utility for researchers in reinforcing justifications for using MMPR and in supporting defense of their methodological decision making when engaging with methodological purists. Following the philosophical discussion, to provide frameworks for researchers looking to utilize a MMPR design, practical strategies for mixing phenomenology with methods grounded in post-positivism are presented alongside current empirical examples of each form of MMPR. The illustrative examples illuminate key features of both descriptive and interpretive MMPR designs, in addition to providing a discussion of the benefits and challenges associated with adopting such an approach. In doing so they highlight different approaches to MMR, MMPR and Phenomenology itself. The final section “Concluding Thoughts” overviews the chapter’s purpose and content and addresses critical questions regarding future development and application of MMPR. It also overviews how MMPR expands current methodological practice and contributes to the advancement of MMR more generally as it provides a philosophical justification and practical strategies for those wishing to utilize such a design approach.

Mixed methods research (MMR)

Increasingly Mixed methods research (MMR) is being adopted within research practice, critically conceptualized, and recognized as the third methodological paradigm alongside Qualitative and Quantitative approaches. Whilst scholars argue that there may not be

an essentialist definition forthcoming for the term Mixed Methods Research (Johnson et al., 2007), dialog surrounding a practical definition remains an ongoing goal for the field. For the purposes of the current chapter, Mixed methods may be defined as “research in which the investigator collects and analyses data, integrates the findings and draws inferences using both qualitative and quantitative approaches or methods in a single study” (Tashakkori and Creswell, 2007, p. 4).

Exploring intersections with phenomenological approaches

The phenomenological method

The term phenomenology is wide-ranging and has been attributed to a historical philosophical movement, a disciplinary field within philosophy, and a range of associated practical research approaches. While phenomenological philosophy has been practiced in many forms for centuries, the movement gained serious momentum in the early 20th century following the publication of pivotal works from phenomenologists including Husserl, Heidegger, Sartre, and Merleau-Ponty. Although their interpretations of phenomenological philosophy differ, there is consensus in their shared belief that human experience is the starting point for philosophy (Todres and Holloway, 2004). This central experiential philosophy informs the phenomenological method in its many guises. Consequentially the central aim of all phenomenological inquiry is to develop a better understanding of individual’s lived experiences through the consciousness of the experienter (Giorgi, 2009). The traditions are united in studying subject’s perspectives of their own worlds, to describe in detail the content and structure of their consciousness and grasp the qualitative diversity of their experiences and to elucidate essential meanings (Kvale, 1996). Phenomenology is therefore focused on both the structure, or *essence* (Husserl, 1965) of human experience, as well as honoring the diverse interpretive variations. The theoretical justification for such an approach is that through uniquely taking a first-person point of view, human beings can be understood from *inside* their subjective experiences (Todres and Holloway, 2004). This is principally achieved by empowering participants to provide in-depth descriptions of their own lived experiences, which can be used as a form of qualitative data and presented as descriptions and/or interpreted. This unique focus rationalizes phenomenology as the ideal method for experiential work within the interpretive paradigm and highlights its potential in representing marginalized voices and reducing power imbalances that exists within traditional research approaches often grounded in positivist philosophy.

The unique strengths and methodological flexibility (Garza, 2007) of the phenomenological method subsequently has led to it increasingly being adopted as a component of mixed methods research approaches. Mixed methods may be defined as “research in which the investigator collects and analyses data, integrates the findings and draws inferences using both qualitative and quantitative approaches or methods in a single study” (Tashakkori and Creswell, 2007:4). This methodological cohesion through combination not only maximizes the key strengths of phenomenology in terms of the exploration of specific lived experiences and empowering potential, but also helps minimize the weaknesses of the phenomenological approach. For instance, while phenomenology has key strengths in exploring individual’s lived experiences through the consciousness of the experienter the tradition provides no way of identifying which experiential phenomenon is most pertinent to an individual or group, therefore being able to orientate the research to the most critical experiences to be studied (Mayoh and Onwuegbuzie, 2015). In addition, critics of phenomenology have highlighted its failure to address the social context of lived experience (Langridge and Ahern, 2003). The following discussion will provide an overview of how multiple forms of phenomenology can be mixed in a philosophically sensitive manner with methods grounded in post-positivism to maximize the strengths and minimize the weaknesses of the phenomenological approach.

The MMPR approach conceptualized

An early systematic review to identify empirical research that incorporated a phenomenological component within MMR (Mayoh and Onwuegbuzie, 2014) demonstrated that 24 articles were published between 2002 and 6 months into 2012. This reflects the early stages of MMPR adoption before formal conceptualization, which were predominantly conducted within the field of health research (70.8%, $n = 17$), with only four additional disciplines being cited: psychology (12.5%, $n = 3$); education (8.3%, $n = 2$); social care (4.2%, $n = 1$); and career development (4.2%, $n = 1$). This earliest recorded MMPR study according to the review was 2003, where only one study was recorded (Langridge and Ahern, 2003). Similarly, the review showed that only one article was published in the following year (Kent, 2004), however by 2011, 7 articles were published, demonstrating a growth in popularity of combining phenomenology as a component of MMR. The increasing practical application of phenomenological methods within MMR approaches led Mayoh and Onwuegbuzie (2015) to deliver a formal conceptualization of MMR that incorporates phenomenology—which they termed “MMPR”; p. 3). In this conceptualization paper they defined MMPR as “research that combines phenomenological methods with methods grounded in an alternative paradigm within a single study” (p. 21). The authors aimed to provide a philosophical justification for using MMPR alongside examples of MMPR in practice to underline several potential models that can practically be utilized in future research. The increasing practical adoption and theoretical discussion and conceptualization of MMPR shows that despite apprehension from advocates of the incompatibility thesis (see, Howe, 1988), and challenges associated with incorporating phenomenology into mixed methods research designs, phenomenological methods provide methodological compatibility with research methods grounded in alternative paradigms such as post-positivism. Since the formal conceptualization, the number of studies citing MMPR has grown with research being conducted within disciplines including child

abuse and neglect (McDonald et al., 2015), counseling psychology (Cobb et al., 2017) and the gamification of education (Kenny et al., 2017).

While the phenomenological method takes a multitude of forms, this chapter will focus specifically on how descriptive and interpretive phenomenology can be interfaced with methods grounded in an alternative paradigm as MMPR. This reflects how MMPR is frequently adopted within academic work, as an early systematic review of MMPR research demonstrated that research combining phenomenological methods with alternative approaches in a single study were predominantly conducted using descriptive (54.2%, $n = 13$) or interpretive (41.7%, $n = 10$) phenomenological approaches (Mayoh and Onwuegbuzie, 2014).

Exploring philosophical compatibility with the phenomenological approach

While historically critics of Mixed Methods Research (MMR) (see Howe, 1998) have adhered to the argument that the philosophical distinctions between qualitative and quantitative methods and accompanying paradigms are too significant to justify combination within a single study, mixed methods researchers have consistently negotiated such differences, making adjustments including using multiple methods within a single paradigm (Johnson et al., 2010) and exploring paradigmatic complementarity (Mayoh and Onwuegbuzie, 2015). These intersections are justified by the shared assumption within mixed methods research that practical research methods are not consistently tied to specific paradigms (Johnson and Onwuegbuzie, 2004). The growing practical adoption (Mayoh and Onwuegbuzie, 2014) and conceptualization of Mixed Methods Phenomenological Research (MMPR) demonstrates that despite the numerous challenges associated with using MMPR, particularly on a philosophical level, multiple phenomenological methods including descriptive (Eidetic), and interpretive (Hermeneutic) phenomenological traditions provide methodological compatibility with methods grounded in alternative paradigms. Table 1 below reviews postpositivist, and phenomenological (descriptive and interpretive) paradigms, and the philosophical assumptions associated with them.

Table 1 A comparison between the philosophical assumptions of postpositive and phenomenological inquiry.

	<i>Postpositivism</i>	<i>Phenomenology</i>	
		<i>Descriptive (eidetic)</i>	<i>Interpretive (hermeneutic)</i>
Ontology (nature of reality)	An objective reality or truth exists, however can never be interpreted fully.	There are multiple constructions of reality. Objectivity relates to the extent to which description is true to a phenomenon. Although experience is subjective, there are features to any lived experience that are common to all persons who have the experience.	There are multiple constructions of reality. Reality is constructed in unique ways depending context and personal frames of reference as individuals engage with the world.
Epistemology (knowledge)	Data are an approximation of objective reality. The ideal of objectivity can only be approximated through taking a critical approach.	Data are based on a subjective reality. The goal of the researcher is to achieve transcendental subjectivity.	Data are based on a subjective reality. These data are produced through the interaction between the participant and researcher, and the researcher's interpretations. There is a need for an orienting framework. People cannot abstract themselves from the world.
Axiology (role of values)	Researcher attempts to remain value free (values must be excluded).	Researcher acknowledges values and bias. The impact of the researcher on the inquiry is constantly assessed so that they do not influence the object of study.	The researcher's values impact the object of study. Expert knowledge on the part of the researcher is valuable.
Methodology (research strategies)	Multiple approaches that may be triangulated.	Methods that focus on obtaining participants descriptions of experience. Variations include Giorgi's (1985, 2009) descriptive phenomenological method in psychology.	Interpretive methods that move beyond the description of core concepts and essences to look for meanings. Variations include interpretative phenomenological analysis (IPA; Smith and Osborn, 2003).

Adapted from Mayoh and Onwuegbuzie (2015, p. 94).

Mixing descriptive (eidetic) phenomenology

Despite the clear paradigmatic tensions between post-positivist and phenomenological inquiry shown in [Table 1](#), the compatibility between methods grounded in these traditions appears more feasible when one considers that the founder of the descriptive (eidetic) method in phenomenology Edmund Husserl (1859–1938) was a mathematician as well as a philosopher. [Husserl \(1970\)](#) viewed phenomenology as a science of essence of consciousness and believed scientific inquiry could provide rich authentic descriptions of phenomena, advancing our understanding of human consciousness and experience ([Husserl, 1976](#); [Dowling, 2007](#)). While he was largely concerned with moving away from traditional forms of positivist inquiry ([Finlay, 2011](#)), Husserl sought to explain how researchers could overcome personal biases, that may stand in the way of achieving the state of pure consciousness by adopting the transcendental-phenomenological reduction, a condition of consciousness in which the researcher forsakes their own lived reality and are able to describe the phenomenon in its pure and universal sense. The very nature of the phenomenological reduction, and the descriptive phenomenologists' aim of recognizing and reducing the role of the researcher through a process called bracketing (i.e., *epoché*; [Husserl, 1931](#)) shows alignment to the post-positivist goal of researcher objectivity, rather than alternative qualitative and phenomenological methods that view qualitative data as co-constructed and inherently biased. Furthermore, [Table 1](#) demonstrates that while descriptive phenomenology acknowledges that human experience is subjective, there may be features to lived experience that are common. According to [Giorgi \(2009\)](#), one of the key characteristics of descriptive phenomenology is the acknowledgment that the essence or bare bones of what constitutes the phenomenon is articulated as the structure ([Holloway and Todres, 2003](#)). It describes the common themes or essential parts from within the experience that identify the phenomenon and can transcend the experiences of different individuals. In honoring that the structure of lived experiences can contain concrete details in addition to ceaseless diversity, the role of object is valued within descriptive phenomenological methods, aligning with the ontological assumptions of post-positivism. Subsequently, MMPR that incorporates a descriptive phenomenological component is increasingly being cited as the methodological approach within research studies.

Illustrative example: Colditz et al. (2019)

[Colditz et al. \(2019\)](#) present MMPR research that integrates a descriptive phenomenological element in observational research exploring narratives about Electronic Nicotine Delivery Systems (ENDS; i.e., vaping devices), using data from the Twitter social media platform on “World Vaping Day”. Given that this was a relatively discrete context, which generated a large amount of qualitatively dense data (5149 “tweet” messages), it was both feasible and beneficial to approach analysis using multiple complementary methods. To assess the quantitative breadth of data, studies on the Twitter platform often assess the frequency of informative phrases, keywords, or hashtags (e.g., #vapelife) to efficiently identify and quantify content of a priori research interest ([Colditz et al., 2018](#)). With respect to qualitative context of this work, researchers understood vaping as a contentious public health topic on the Twitter platform (e.g., politicization, health misinformation). As health scientists, the researchers decided it would be important to bracket out preconceived notions about the underlying health implications in order to focus on essential experiences of the World Vaping Day phenomenon. Bracketing is germane to descriptive phenomenology in health contexts and so this was chosen as a favorable approach to enhance rigor of the qualitative synthesis ([Lopez and Willis, 2004](#)). While the phenomenological and quantitative procedures were conducted independently, the data collection phases were informed by the concurrent analytical approach ([Creswell and Plano-Clark, 2017](#)), where the methods are given equal priority, analyzed independently, but interpreted together.

The authors developed a broad codebook containing themes that were relevant to ENDS propagation, focusing on positive and negative sentiment surrounding particular categorical themes. By categorically coding the data within this post-positivist framework, prevalence of identified themes could be quantified, and inter-rater agreement statistics calculated to demonstrate reliability of coding. In order to not limit the experiential data, and to honor the paradigmatic assumptions of the phenomenological element, observations relating to themes that didn't fit into the conceptual framework were collected to integrate parallel data analysis and synthesis, allowing for both structured (coded utterances in quantifiable categories) and unstructured data (notes, observations and examples). The unstructured data were then synthesized within a descriptive phenomenological research framework. In combining thematic prevalence estimates with descriptive methods for phenomenological contextualization, the authors were able to achieve both quantitative breadth and rich descriptive qualitative depth within their study. This also contributed to the methodological research narrative by outlining a strategy for utilizing descriptive phenomenology within a mixed methods study of primary social media data. In doing so, the authors were able to address a criticism of phenomenological work, that it can be alienating due to the dominance of phenomenological research that is prohibitively dense with philosophical theory to those less familiar with the concept ([Caelli, 2001](#)).

The descriptive MMPR approach made a unique contribution to the research narrative exploring the intersection between social media use and phenomenology that generally relies on interview data and fails to recognize the potential experiential depth of naturalistic primary online data ([Colditz et al., 2019](#)). While phenomenological purists may reject the idea that meaningful experiential data can be obtained through social media observation, the researchers in this study maintained a narrow scope of observation in order to explore a cohesive landscape of experiences within a specifically defined social context. In contemporary phenomenological approaches, such data might be obtained from interviews and thus the scope of data would be limited by the interview boundaries. Then horizons (i.e., units of meaning contextualized along the phenomenal landscape) would emerge from quotes and impressions

identified from interview transcripts. In the context of Colditz et al. (2019), the scope was limited by searching for any tweets containing ENDS-related keywords on the third annual “World Vaping Day”. As tweets are relatively short (280 text characters), Twitter users convey concise units of meaning within brief utterances and associated multimedia content (e.g., emoji, links, images and video). This provided observational researchers with a topically cohesive yet diverse landscape of horizons to synthesize. While results indicated that direct references to World Vaping Day were relatively rare in the data, it was clear that this online event was experienced differently among various interest groups (e.g., ENDS manufacturers, former tobacco smokers, health policy advocates). Overall, the sentiment of tweets mentioning ENDS was positive or enthusiastic (>3:1 ratio vs. negative sentiment), with the exception that policy-related tweets tended to be more negative (e.g., discontent over ENDS regulation). Phenomenological inquiry allowed for exploration of nuanced social patterns and themes in the data (e.g., #vapecommunity hashtag was primarily used by a niche of individuals promoting ENDS over smoking, #vapelite and #vapelyfe were more commonly used to directly promote ENDS products). Additional perspectives on the vaping phenomena included a sense of authenticity or “coolness” around individuals who used ENDS to quit smoking and those who were knowledgeable about complex aspects of ENDS devices (e.g., modifying components, “vape juice” flavors). This enthusiasm was contrasted by jokes ridiculing younger ENDS users, for using ENDS to appear cool rather than to quit smoking. The researchers also distinctly identified ENDS users’ animosity toward the “big tobacco” companies that entered the ENDS market then championed stricter US government regulations (running counter to the interests of ENDS users and smaller commercial manufacturers). Through this MMPR synthesis, the researchers came to understand World Vaping Day as a window into a more complex vaping culture, within a broader online landscape dominated by commercial interests, social comparisons, and—to a lesser extent—health-related discourse that researchers might otherwise anticipate and focus intently on.

In line with previous argument made in this chapter, Colditz & colleagues acknowledged the compatibility between phenomenology and mixed methods approaches. They recognized the descriptive method’s powerful ability to control for researcher bias through acknowledging and reducing the role of the researcher (bracketing), requiring researchers to recognize and monitor the relationship between their subjective experience (e.g., what topics might be of health importance) and objective reality (i.e., what was the essential experience of World Vaping Day). In doing so they state that this approach allowed the researcher to identify and reduce personal bias (Arslan and Yildirim, 2015) while recognizing both an ontological imperative to acknowledge the objective existence of a phenomenon with the epistemological assumption that individuals interpret phenomena subjectively. This was achieved through a process of synthesizing notes and observations into organized narratives that could be utilized to pursue didactic inquiry among coders and help uncover the structural aspects of vaping culture expressed in this context. The synthesis of qualitative data was made possible through the development of a structured codebook and coding process, complemented with annotations, quotes and narratives, and critical reflections through a phenomenological lens. These provided rich context that could contribute to and move beyond the conceptual framework provided by the coding categories. In converging the phenomenological synthesis into the categorical results narrative, the authors were able to move beyond the reporting of reductive statistics and key words and integrate deeper experiential themes that helped frame a more essential understanding of vaping culture in this context.

Observational social media research remains a relatively atypical application for MMPR. This particular example was chosen to demonstrate how descriptive phenomenology can be successfully incorporated into highly novel MMPR approaches. Thus, MMPR holds some promise in well-scoped observational research contexts, particularly for understanding social media phenomena where individual experiences align in complex ways. This may be considered a beneficial extension of the descriptive phenomenological framework—rather than a separate social media research framework—insomuch as researchers strive to maintain fidelity of the philosophical considerations and commonly accepted procedures for descriptive MMPR. These considerations of course remain important for contemporary research approaches that might rely on interview or self-report data.

Mixing interpretive (hermeneutic) phenomenology

While Husserl is oft credited as the founding father of descriptive phenomenology, it is his student Martin Heidegger (1889–1976) that is widely regarded as the innovator behind the interpretive phenomenological method. Heidegger (1962) contested that “the meaning of phenomenological description as a method lies in interpretation” (p. 61), viewing hermeneutic description and interpretation as a way of analyzing being. Unlike descriptive (eidetic) phenomenology, interpretive (hermeneutic) approaches put significantly less weight on the phenomenological attitude and bracketing to minimize the impact of researcher bias. Alternatively, they emphasize the co-constructed interpretations of the individual’s life world as well as the individual’s natural orientation to the phenomena (Van Manen, 1990). In this sense, interpretive phenomenology informed by Heidegger moves away from Husserl’s phenomenology as a science of essence of consciousness, rejecting the lingering notes of positivism, and moves into a less cognitive existential framework. Consequently, mixing interpretive phenomenological approaches with methods grounded in the postpositivist paradigm poses more significant challenges due to the competing axiological assumptions with post-positivism at a paradigmatic level (see Table 1). Despite this, scholars have suggested philosophically sensitive models for integrating interpretive phenomenological approaches into MMPR (Mayoh and Onwuegbuzie, 2015). In describing the interpretive method, Van Manen (1990) defines the process of orienting to the phenomenon within interpretive phenomenology, a stage which is conducted prior to focusing in on a specific phenomenological question involving focusing on identifying what lived experience would be the most relevant focus for phenomenological inquiry. Based on this practical feature of

interpretive methods, [Mayoh and Onwuegbuzie \(2015\)](#) suggest there is a strong rationale for the inclusion of a quantitative preliminary phase to orient toward the most valuable lived experience for phenomenological inquiry. In addition, we conclude there is a strong rationale for sequential, interpretive MMPR that utilizes an initial quantitative phase to give additional context, structure and focus to the secondary interpretive phase.

Illustrative example: Zamariola et al. (2019)

In their 2019 study, Zamariola et al. used a sequential MMPR approach adopting a preliminary quantitative phase for orientation, and a subsequent qualitative phase for context, to enrich an exploration into the relationship between interoception (the ability to perceive one's inner bodily feelings) and emotion regulation. The study contributed to existing literature in the field, which focused mainly on questionnaires or mood induction techniques in isolation and provided inconsistent results and low reliability of measures. The methodological approach encouraged rich, focused experiential descriptions from the participants' perspectives to better understand the lived experience of the relationship. Phase one of the study included a heartbeat counting task, and the administration of quantitative questionnaires designed to assess interoceptive sensibility, "the self-perceived sensitivity to internal bodily sensations" ([Pearson and Pfeifer, 2020](#), p. 3). This allowed the research team to develop subsamples of participants scoring low, average, and high interoceptive sensibility, so that the subsequent phenomenological phase could explore their perceived bodily awareness and uncover how this influenced emotional awareness. Participant quotes from semi-structured interviews provided evidence for the phenomenological themes and enabled enriched insight to the relationship and its lived experience.

The qualitative phase of this study utilized Interpretative Phenomenological Analysis (IPA) ([Smith, 1996](#)). This method enables exploration of how participants make sense of experience, closer to Husserl's focus on the contents of consciousness than on Heidegger's focus on description of lifeworld experiences. IPA recognizes that lived experience cannot be accessed directly and uses detailed analysis to follow a chain of connection in participant accounts from embodiment to language to emotion to cognition ([Frost, 2021](#)). By aiming to access mental phenomena, IPA enables greater understanding of how, for example, strategies to manage negative emotions are managed, making it an appropriate method for this study. It is tied to a double hermeneutic which recognizes that researchers seek to make sense of how participants make sense of their experiences. It is idiographic—focusing first on in-depth analysis of each participant account before moving to examination of similarities and differences across the accounts. Detailed insight to patterns of meanings and reflections on shared experiences are produced in the form of themes that give insight to strategies, abilities and complexities of experience are enacted and managed.

Three themes were discovered: Interoceptive Abilities, Emotional Abilities, and Influences on Interoceptive and Emotional Abilities. The Interoceptive Abilities theme described how all participants found the heartbeat counting task difficult to perform. Perception of heartbeats was challenging for all and those participants with low interoception had the greatest difficulty in perceiving cardiac signals. This supports existing studies that suggest that performance in this task relies largely on non-interoceptive processes and on general beliefs about heartbeat rates ([Desmedt et al., 2018](#); [Ring et al., 2015](#); [Zamariola et al., 2018](#)). The Emotional Abilities theme showed that some participants found negative emotions harder to identify, while others were able to recognize these emotions but had difficulty in regulating them. The use of the subjective phenomenological method enabled the complexity of recognizing and verbalizing emotions to be recognized. The third theme identified a range of strategies used by participants to manage negative emotions. These included talking to oneself, using food as comfort, and engaging in physical exercise, but also that the strategies provided varying degrees of relief. The study also found that participants with high interoception described seeking a balance between mind and body and reported being more self-focused and motivated to use techniques such as psychotherapy, mindfulness, and yoga to understand more about their inner life. Better emotion regulation was suggested as being more achievable by individuals with a positive and active attitude to managing negative emotions.

When considered alongside the quantitative phase of the study, the in-depth analysis of the interviews not only provided insight to the relationship between interoception and emotion regulation but also challenged the reliability of the heartbeat counting task. The study calls for further qualitatively orientated research to develop new techniques to assess interoceptive accuracy, and importantly, shows that interoception and emotion regulation are subjectively related.

Strategies for mixing within MMPR studies

Based on the theoretical discussion and illustrative examples, we support the notion that there is a strong justification for the inclusion of multiple forms of phenomenology within mixed methods studies. Specifically, the philosophical assumptions outlined in [Table 1](#) support our assertion that descriptive phenomenology has compatibility when utilized concurrently with methods rooted in the post-positivist paradigm, while there is a stronger justification for the combination of interpretive phenomenology sequentially within MMPR studies. In addition to this suggestion, the inductive nature of both forms of phenomenological inquiry encourage reasoning for the integration of an explanatory quantitative proceeding phase within sequential mixed method designs to test phenomenologically generated concepts ([Mayoh and Onwuegbuzie, 2015](#)). That being said, to increase the utility and scope

Table 2 Models for mixed methods phenomenological research.

<i>Model</i>	<i>Description</i>	<i>Purposes</i>
phen → QUAN or phen → QUAL	Preliminary phenomenological method with priority given to the method from an alternative paradigm.	The preliminary phenomenological stage is used to generate theory about the nature of lived experience that can feed into a larger QUAN QUAL study. This approach is especially valuable when the study requires an overall more deductive thrust.
quan → PHEN or qual → PHEN	Preliminary method from an alternative paradigm with priority given to the phenomenology	The preliminary quan/qual phase is used to orientate the predominant PHEN stage to the most relevant and interesting phenomenon. This model is valuable when the study requires an overall more inductive thrust.
QUAN → phen or QUAL → phen	Preliminary method from an alternative paradigm which is also given priority.	The secondary phen stage is used to explore unanticipated QUAN or QUAL findings. This model is especially valuable when the study requires an overall more deductive thrust.
PHEN → quan or PHEN → qual	Preliminary phenomenology which is also given priority.	The secondary quan/qual phase is used to help improve the utility and generalizability of phenomenological findings. This approach is valuable when the study requires an overall more inductive thrust.
quan + phen or qual + phen	Concurrent approach. Normally methods have equal priority (however, it is possible to give priority to a single method depending on the overall thrust of the study).	Within this model, phenomenological and complementary data are collected concurrently to cross-validate or to confirm findings.

Adapted from [Mayoh and Onwuegbuzie \(2015: 104\)](#).

of MMR as a methodological approach, future theoretical and practical work should not be limited to discussing and utilizing explicitly sequential or concurrent approaches based on the phenomenological approach adopted, as mixed methods researchers strive to develop more innovative and philosophically sound models for mixing. In contributing to this discussion, [Mayoh and Onwuegbuzie \(2015\)](#) propose several practical models for using MMR as a research design (see [Table 2](#)). In these models → or + is used to represent the sequence decision (→ for moving sequentially and + for working concurrently) and capital and lower-case letters are used to characterize the priority decision (QUAN or QUAL for principal method, quan or qual for complementary method) in line with previous MMR literature ([Morse, 1991](#); [Morgan, 1998](#)).

Concluding thoughts

The purpose of this chapter was to provide both a philosophical and practical discussion regarding the intersection between phenomenology and methods grounded in post-positivism within a single study, and to showcase two practical examples, one using descriptive (eidetic) and one interpretive (hermeneutic) phenomenology within mixed methods research. In doing so this chapter makes a unique contribution to the field of educational research and practice in providing a communicative representation of how phenomenology can be incorporated as a part of MMR studies. Furthermore, the humanizing potential of MMR provides great utility within educational research practice that oft deals with both human lived experiences and structure of learning organizations.

Specifically, in this chapter we focused on the integration of two forms of phenomenology that [Mayoh and Onwuegbuzie \(2014\)](#) have previously identified as the most often utilized within this form of research; descriptive (54.2%, $n = 13$) and interpretive (41.7%, $n = 10$) phenomenological approaches ([Mayoh and Onwuegbuzie, 2014](#)). However, it is important to note that alternative phenomenological methodological approaches, for example the dialogical phenomenological approach ([Stawarska, 2009](#)), have compatibility with post-positivism on a paradigmatic level, as axiologically they focus on empowering participants to take a leading role within the research process and adopt a research-facilitator role, thus minimizing the role of the researcher, and therefore, as with descriptive methods, helps eliminate individualist bias that honors subjectivity in some phenomenological approaches. Future theoretical work on MMR should focus on a more road conceptualization of phenomenological methods, and what alternative phenomenological approaches offer as components of mixed methods studies.

While the illustrative examples demonstrate great utility in integrating phenomenology within MMR studies, we advise all those considering MMR pay serious consideration to the cohesion between the multiple research methods, as well as thinking about the implications and potential associated with the priority and sequencing decisions, and how this relates to the unique philosophy of each approach within each methodological element.

Grounded theory is one of several mainstream qualitative methodologies that have demonstrated adaptability to diverse approaches, including mixed methods. Leading voices in the development of grounded theory, including its founders, have long singled receptivity to using both qualitative and quantitative data with grounded theory. For example, in her framing of a constructivist approach to grounded theory, Charmaz extended the idea of its adaptability to mixed methods when she observed "an emerging grounded theory can indicate needing more than one type of data and can incorporate more than one type of analysis" (2014, p. 323). Similarly extending the idea to encompass not just data but analytical procedures, Walsh wrote: "A [grounded theory] may thus be generated using qualitative and/or quantitative data, methods, and techniques" (2015, p. 536). No one has accepted the challenge to flesh out a methodological rationale for partnering grounded theory with mixed methods.

At its most basic level, mixed methods research can be defined as the combination of qualitative and quantitative data or analytical procedures. It is distinguished from multi-method research in its conviction of the contribution of integrating data collected through different methods in purposeful ways. Multi-method is the preferred term for any combination within the same tradition, including data collected through multiple qualitative or multiple quantitative approaches.

Although often mistakenly applied as simply an approach to coding qualitative data, grounded theory is a methodology with its own distinct analytical logic. The methodological foundation of grounded theory encompasses a set of procedures or tools. In my teaching, I have found it useful to refer to studies that limit their use of grounded theory to a set of coding procedures (open, focused, axial) as "little GT." "Big GT" recognizes that the ultimate purpose of those tools is to build theoretical insight.

Mixed method grounded theory (MM-GTM) is a methodology that does not just add quantitative data to what is otherwise a qualitative approach. MM-GTM is a radical new way to conceive of grounded theory that embeds the dialectical logic of mixed methods in the constant comparative method and grounded theory procedures. Its aim is not prediction but to develop a theoretical explanation that conceptualizes the interrelationships between concepts and provides an explanation for why and how these occur.

Purpose

Methodologically oriented literature is just beginning to emerge about MM-GTM (i.e., Creamer, 2018b; Guetterman et al., 2017; Johnson et al., 2010; Johnson and Walsh, 2019; Walsh, 2014, 2015). These have concentrated on its usefulness (i.e., Walsh, 2015), ways to evaluate its quality (i.e., Guetterman et al., 2017), the variability in the way studies with this design have been implemented (i.e., Johnson and Walsh, 2019), and introduced the potential for a mixed methods approach to be embedded in the core set of procedures (i.e., Creamer, 2018b). With no lack of examples of MM-GT now in print, the time is right for the forward thinking required to advance a methodological rationale for partnering grounded theory and mixed methods.

The goal of this encyclopedia entry is to offer guidance for those striving to incorporate grounded theory in a mixed method project in ways that honor the integrity of each. The purpose of the entry is to present an argument for the methodological

compatibility between mixed methods and most approaches to grounded theory. It is also to demonstrate different ways it can be accomplished and identifies different reporting standards that are relevant to MM-GTM. It articulates the view of MM-GTM as a distinct methodology that includes an analytical logic and set of core analytical procedures that produce a synergistic outcome that is greater than the sum of its distinct parts.

Methodological compatibilities between mixed methods and grounded theory

“Methodological dynamism” is a term that has been used broadly to describe to how methods evolve and remain viable over time (Ralph et al., 2015). Both mixed methods and grounded theory have been characterized as methodologies that are adaptable to diverse circumstances and methodological priorities. Innovative applications of each continue to emerge. Highlighting the ways researchers adapt grounded theory to diverse circumstances, Seidel and Urquhart (2013, p. 237) observed: “Grounded theory method (GTM) is an evolving method that is subject to idiosyncratic interpretation and flexible deployment.” The way an investigator deploys a methodology is an expression of his or her ontological and epistemological perspective and the wider social and intellectual strains of thought that influence a time period (Ralph et al., 2015).

There are multiple areas of the overlap between the methodological assumptions of grounded theory and mixed methods that provide a rationale for their pairing. Areas of methodological compatibility extend to (a) the iterative nature of the constant comparative method, (b) abduction as an analytical logic, (c) the adaptability of both mixed methods and grounded theory to different ontological (the nature of reality) and epistemological (legitimate ways of constructing knowledge) paradigms, and (d) the way it accommodates complexity. The role of verification is one topic where the methodologies differ (Dey, 1999). Each of the areas of overlap are discussed in the next section.

The iterative exchange embedded in the constant comparative method

Although the idea has been neglected in the methodological literature about either grounded theory or mixed methods, one of the principal arguments for the compatibility between the two is based on an endorsement voiced by the founders of grounded theory, now more than fifty years ago. The constant comparative method is an approach to analysis conventionally framed to mean that data analysis and data collection co-occur. Analysis begins as the first unit of data is encountered.

In MM-GTM this necessarily means that in at least one phase of the research process, quantitative and qualitative analysis unfolds simultaneously. This involves an iterative process where at some point in the analytical process qualitative and quantitative data are *not* kept separate during analysis. This process is facilitated by merging data into a single spreadsheet or database.

MM-GTM is adaptable for use with an existing data set. This could be the case, for example, with a study involving social media posts or a body of documents like case notes, where analysis could be launched with a small subset of the data. In this scenario, theoretical sampling might involve dipping back into a data set to target the selection of cases to further elaborate the properties of a core construct.

The analytical logic of abduction

A second area where the methodological assumption of grounded theory and mixed methods overlap is about abduction as an analytical logic. Abduction is one of three approaches to reasoning that include induction (generalizing from the specific to the general) and deduction (generalizing from the general to the specific) (Locke et al., 2008). In MM-GTM, abduction is the process of alternating between an exploratory and a confirmatory stance to systematically generate and test a series of alternative explanations.

Several noted methodologists maintain that it is more accurate to describe the analytical process at the center of grounded theory as an abductive one rather than an inductive one (e.g., Bryant, 2017; Timmermans and Tavory, 2012). Co-editor with Kathy Charmaz of the influential *SAGE Handbook of Current Developments in Grounded Theory* (2019), UK academician Anthony Bryant associated abduction as an analytical logic with one of the co-founders of the methodology. He wrote that while in later writing Barney Glaser maintained his advocacy for the idea of pure induction, the more pragmatic one of the original pair, Anselm Strauss, gave some attention to abduction when he struck out on his own (Bryant, 2017). Bryant wrote: “There is now growing recognition that although the process of induction certainly has a role in grounded theory, it is abduction that needs to be understood as a far more important – indeed *essential* (italics his)- aspect” (2017, p. 269).

In building a case for the pragmatic foundation of grounded theory, Morgan (2020) extends the logic of abduction to theoretical sampling and brings to light its link to verification. He suggested that purpose of theoretical sampling is not only to flesh out the properties of categories but to explore and elaborate working hypotheses through an abductive process that alternates almost seamlessly between induction and deduction (Morgan, 2020). Theoretical sampling is not a one-time process in this approach.

Although this is at odds with a “classic” or “formal” approach to grounded theory, on-going engagement with the literature is at the center of the abductive process. Abduction occurs within the context of previous knowledge, including other theoretical frameworks (Kelle, 2019). Abduction “assumes extensive familiarity with existing theory at the onset and throughout every research step” (Timmermans and Tavory, 2012, p. 173). The active role of the literature throughout an abductive approach to analysis, means that

the analytical process is not as purely inductive as the founders first envisioned. Investigators often reach into unfamiliar bodies of literature to make sense of puzzling findings throughout the research process.

Adaptability to complexity

The complex nature of individual actions and interactions within multi-layered socio-cultural context is a third rationale for the compatibility between mixed methods and grounded theory (Guetterman et al., 2017; Johnson et al., 2010). “We believe that the human world is especially rich and complex, and that MM-GT can offer an important method for understanding complexity” Johnson et al. observed (2010, p. 72). Complexity requires a dynamic research design that can accommodate changes in the research environment and navigate empirical findings that do not always cohere in expected ways (Poth, 2018).

There are multiple indicators of a complex research design. Three signatures of a complex research design include (a) when the core construct is multi-dimensional and framed as embedded in a socio-cultural context, (b) data are collected from multiple levels of an organization, or (c) when participants are distributed across geographically diverse settings (Poth, 2018). In a school setting, for example, this might include teachers, parents, students, and administrators in multiple different settings. Diversity among collaborators is another dimension of complexity (Poth, 2018). Saturation of the properties of all categories can be an elusive standard to achieve in complex research designs.

Compatibility with multiple paradigms

A fourth way that the methodological grounding of mixed methods and grounded theory is compatible is that they are both adaptable to diverse epistemological perspectives. Both grounded theory and mixed methods have been adapted by investigators operating from diverse epistemological paradigms. Urquhart (2013, p. 36) observed, for example, that grounded theory can be “appropriated by researchers with different assumptions about knowledge and how it can be obtained.” Grounded theory has been approached from diverse paradigmatic perspectives, post-positivism, interpretivism, constructivism, and postmodernism (Sebastian, 2019).

As with grounded theory methodology, researchers have approached mixed methods from the perspective of many different paradigms (Creamer, 2018a). The original textbooks to appear about mixed methods that first emerged between the late 1980s and 2003 are characterized by Denzin (2010) as a mirror of the post-positivist and quantitative perspective that was dominant at the time. The postpositivist orientation of these influential early textbooks may explain why quantitative methods are prioritized in the first generation of research to carry the mixed methods label. During this period, there were few opportunities for training in qualitative methods, much less mixed methods. Lack of familiarity with qualitative methods and their variety, may explain the all too common practice of applying a quantitative logic to the analysis of qualitative data by relying on counting and quantification.

Morgan proposed that a pragmatic approach guides most social science research methodology, including mixed methods (2007) and grounded theory (2020). Without overlooking its link to a pragmatic grounding, others writing about mixed methods affiliate with the lens of dialectical pluralism as a guide for investigators committed to the exploration of diverse perspectives (e.g. Johnson, 2012) or a commitment to social justice that is associated transformative research agenda. Researchers joining interdisciplinary endeavors are likely to need competencies in more than one method and more than one paradigm.

Distinct contributions of each method

That each method makes a distinct contribution is a second part of the methodological rationale for MM-GTM. For grounded theory, this includes assurances that there will be a genuine qualitative or inductive phase. An additional contribution is that it offers a set of procedures for data collection and analysis that are absent from mixed methods. Each of these can offset an inclination to downplay the qualitative portion of MM-GTM. The unique contribution of mixed methods includes a push to be inclusive of a broad range of sources of data, a logic that justifies attention to dissonance, and more options for sampling, verification, and understanding exceptions.

The topics of verification or confirmation and the treatment of exceptions are two areas where it is possible to pinpoint what can be gained through the pairing of mixed methods and grounded theory. Leading voices in the different approaches to grounded theory, including its founders, do not award much attention to procedures that contribute to verification, seeing the purpose of grounded theory as developing theory rather than verifying it (Dey, 1999). The same ambivalence extends to exceptions and outliers. Charmaz acknowledges the role of confirming hunches and promising leads but resists the idea of systematic attempts at verification in grounded theory (Morgan, 2020). There is little justification for verification in constructivism because all truth claims are equally valid (Bryant, 2009). Similarly, dissonance is only prioritized as a source of original insight in postmodern approaches to grounded theory (Aparmian et al., 2017).

There is as much variability in the ways that MM-GT studies have been implemented as there is in other types studies. In the next section, we shift from more abstract, philosophical issues to considering different research designs where ways the two can work in tandem. The first approach is a classic one in that it considers studies that are launched, much like instrument development, to develop and test and theoretical framework. Integration often serves multiple purposes in both of these designs.

Two approaches to implementing a MM-GT study

There are a wide variety of ways that MM-GTM can be implemented (Johnson and Walsh, 2019). Referring to it as mixed grounded theory (MGT), Johnson and Walsh wrote: “There are perhaps an infinite number of versions of MGT to be explored and ‘invented’ by practicing researchers in the production of knowledge” (p. 523). One implication of this statement is that there is no formulaic template for implementing a MM-GTM study. The more widely used approaches range from those that sequester the analysis of qualitative and quantitative into separate phases to those that employ a more iterative design where there is an on-going exchange between the qualitative and quantitative approaches in more than one phase of the research. Each achieves integration in a different way. Two different approaches to implementing a MM-GTM study are described in the next section.

Linking distinct qualitative and quantitative phases to develop and verify or elaborate a grounded theory

The ability to generate a theory qualitatively and to test it quantitatively was the first purpose envisioned for MM-GT (i.e., Johnson et al., 2010). Both Johnson et al. (2010) and Walsh (2015) advocate for the potential of MM-GTM to generate and test formal grounded theory that awards comparable recognition of findings emerging from the analysis of qualitative and quantitative data. Any claim that data from the qualitative and quantitative phases are given equal weight, is mitigated, however, by an improbably small sample size for the qualitative phase.

A formal grounded theory is often expressed in a visual display or model that identifies the core phenomenon, contextual and more local individual and social conditions that influence the phenomenon, actions/strategies, and consequences or outcomes (Johnson et al., 2010). One way that mixing occurs is through the construction of a composite model that combines qualitatively and quantitative derived constructs (Johnson et al., 2010). This type of theoretical framework has utility in the evidence-based movement when it provides a theoretical justification for a new activity or program.

Table 1 summarizes a number of the design features of MM-GTM studies that use a research design with self-contained phases for the qualitative and quantitative data collection. These can occur sequentially or concurrently. The table summarizes some common trends, without suggesting that there is not substantial variety in the ways these are implemented. The table identifies purposes for this design, how mixing is achieved, and the type of priority that is often awarded for each phase, among other features.

Mixing in this approach to MM-GTM occurs through linking or connecting of qualitative and quantitative phases of data collection and analysis. In a sequential design, as for instrument development, the second phase is influenced by the one that precedes it, but it can be disaggregated for purposes of future publications. This type of design often reflects a quantitative priority. Some methodologists take the position that the multi-method label is most appropriate for a project undertaken with the purpose of developing an instrument where the qualitative data are mined exclusively for purposes of constructing an instrument or research protocol.

There are some advantages to a research design with separate qualitative and quantitative phases of data collection and analyses. One benefit is to time management when research unfolds in a predictable way that aligns more closely to an original plan than those with an emergent quality. The value-added of the approach might be described as additive in that the purpose and contribution of each method is readily identifiable. Additional advantages of this design apply to introducing efficiencies to a collaborative project. It accommodates a clear division of labor, enabling collaborators working at a distance to conduct the research in a relatively independent manner. The two-phase design makes it possible for distinct epistemological philosophies to co-exist.

Even in a two-phase design where data analysis and data collection are conducted relatively independently, it is not unusual for preliminary findings from the analysis of different sources of data to conflict. It is not uncommon in a research project involving the implementation of an intervention for the quantitative data to fail to provide statistical support for the intended outcomes, while the qualitative data paint a more nuanced picture.

Table 1 Linking distinct qualitative and quantitative phases to develop and verify or elaborate a grounded theory.

<i>Design feature</i>	<i>Characteristic of MM-GTM</i>
Type of Mixing	Linking
Principal Purpose(s)	Develop and test the applicability of a grounded theory to more than one setting; develop a theoretical basis for instrument development.
Design	Two-phase, sequential mixed method design
Priority	Equal or unequal
Expertize of Collaborators	Likely to be distinct
Level of Interaction among Collaborators	Can be minimal
Likely Sources of Dissonance	Quantitative data fail to support the effectiveness of an intervention.
Examples	Bussing et al. (2011), Howell Smith et al. (2019), Kawamura et al. (2009).

Interactive designs with integration through embedding

The display of variety is most evident in MM-GTM studies and projects that are implemented with an interactive design where integration occurs at multiple points in the research cycle and serves multiple purposes. These can be planned from the onset as multi-stage designs with multiple stages of data collection and may include different combinations of sequential, parallel or convergent approaches with exploratory and explanatory phases. These can also include pairing with other research methodologies, like case study or participatory community-based action research. These types of projects might be described as having a “mixed priority”, rather than an equal one, when key insights emerge from analytical procedures that bring different sources of together and when the sum is greater than the parts (Creamer, 2018b).

The idea of research design is generally thought to apply to how a research project is planned, but it has dual meanings in that it extends to how research is actually implemented as it adapts to a dynamic research environment or unexpected findings (Hunter and Brewer, 2015). It often happens that an initial plan for a tidy two phase, sequential mixed method design evolves to a more complex or messy one. This can occur, for example, when the outcomes of an intervention are not in line with what was predicated from prior knowledge. Similarly, researchers may need to make unplanned detour to collect more data or to conduct additional analysis to find an explanation for why the quantitative results fail to document the effectiveness of an intervention (Creamer, 2018b). Other factors can contribute to complexity, such as differences of opinion among collaborators or an unexpected inability to support a long-standing theoretical assumption. There are different labels for the type of integration between findings from different qualitative and quantitative research methods that characterize an interactive mixed method design. A type of integration referred to as “embedding” is particularly well suited to grounded theory because of its link to the back and forth between analysis and data collection that is part of the constant comparative method. The “hallmark” of embedding “is recurrently linking qualitative data collection to quantitative data collection at multiple points” (Fetters et al., 2013, p. 2141). In a fully integrated mixed method approach to grounded theory (FIMM-GTM), there is an active exchange between different sources of data at multiple stages of the research process (Creamer, 2018b). A fully integrated approach can extend to working with multiple sources of qualitative data. Collaboration is often characterized by a high level of interaction and some overlap in expertise (Creamer, 2020).

Table 2 provides an overview of some of the key design features of an interactive MM-GTM design.

We see more examples of this approach to MM-GTM than with the first, more compartmentalized approach where integration occurs through linking.

A long-standing and very likely irreconcilable debate about the role of the literature in developing theoretical insight with grounded theory procedures very likely at the root of why the potential for MM-GT to extend or elaborate an existing theory has been disregarded (Creamer, 2021). The failure of findings from different sources of data to cohere, for example, led Kaplan and Duchon (1988) to dig more deeply into group differences. Similar encounters with incongruity have led to unexpected insight about the multi-dimensionality of a construct, revealed constructs that elaborated conditions that influenced the achievement of an expected out, or to trace causation suggested by a time-ordered process (Creamer, 2020).

An iterative approach to MM-GTM that engages data from different sources at multiple points during data collection and analysis has both advantages and disadvantages. The principal advantage is an enhanced potential to tackle the complexity that is inevitable whenever research is conducted in a dynamic research setting, requires multiple layers of expertise, considers constructs like identity or sustainability that are multi-dimensional, and embeds understanding of a phenomenon research within the type of multi-layered socio-cultural context identified by Plano-Clark and Ivankova (2016).

Disadvantages of an iterative approach to integrating findings from different sources of data in MM-GTM relates to the unpredictability and complexity introduced by integration. An abductive process can translate to a commitment of time and resources in analytical detours that ultimately prove unproductive. Finding the appropriate terminology to communicate succinctly with a diverse interdisciplinary audience is an additional challenge.

Table 2 Interactive designs with integration occurring during analysis.

<i>Design feature</i>	<i>Characteristic of MM-GTM</i>
Type of Mixing	Embedding
Principal Purpose(s)	Elaborate existing theory, explain dissonant or unexpected findings
Design	Analysis of one source is influenced by findings from another and vice versa.
Priority	Mixed
Expertise of Collaborators	Likely to overlap
Level of Interaction among Collaborators	Often characterized by high levels of interaction during analysis.
Likely Sources of Dissonance	Unexpected findings that emerge from integration
Examples	Catallo et al. (2012), Kaplan and Duchon (1988), Walsh (2014), Wesely (2010), Westhues et al. (2008)

Gauging the quality of MM-GTM

An expansive view of criteria for weighing the merits of a MM-GTM include indicators related to the research methods (transparency, saturation) and the analytical and conceptual outputs (utility and originality) that apply to all research methods. Methodological transparency or precision about describing core procedures, including integration, is the principal criterion for judging quality in all but a few of the standards of reporting for mixed methods. On the other hand, saturation is positioned as a necessary condition of research quality in grounded theory. The application of saturation, transparency, utility, and originality as indicators of the quality of reporting are discussed next.

Saturation

Saturation is part of the core procedures in grounded theory. It is a signal that data collection is sufficient when no new properties of a category emerge that contribute to further analytical insight. The expression, “saturation,” is applied relative to theoretical categories. Reaching a judgment about saturation includes consideration of disconfirming cases. Saturation is accomplished when no new properties about a category emerge (Charmaz, 2014). “Saturation means more than a one-time check,” Charmaz wrote (2014, p. 215). Saturation is linked to theoretical sampling and complicates any attempt to establish sample size ahead of time. The more multi-dimensional the core construct and complex the model, the less likely that saturation can be achieved. An expectation to saturate categories and their properties can have an impact on a final composite model. It is very likely to produce a more streamlined or parsimonious final theoretical model.

Methodological transparency

With few exceptions, virtually all of the standards of quality that have been adapted for mixed methods emphasize transparency about the research procedures, including integration, and the utilization of appropriate terminology to label the mixed method design. In MM-GTM the expectation for methodological transparency extends to using appropriate terminology and an explanation about how core grounded theory analytical procedures, like theoretical sampling, were executed. The emphasis on methodological transparency is evident in the first analysis of a body of MM-GTM research articles where quality was assessed by the number of core grounded theory procedures that were identified and explained (e.g., Guetterman, et al., 2017), without attending to integration.

Transparency about research methods is strongly related to its utility for other researchers, but it is no guarantee that a study is rigorous or that the conclusions are warranted. In MM-GTM, evaluative criteria extend to finding a way to warrant the conclusions, including key themes or constructs and relationships depicted in a final, composite theoretical model. The process of warranting a conclusion refers to documenting the link between data and key findings. In mixed methods, findings are often warranted through a table or figure or table that incorporates qualitative and quantitative data and traces the link to key themes or hypothesis.

Utility and originality

Utility and originality have been put forward as generic criteria to reach a judgment about the quality of the theoretical insight produced through a systematic set of procedures (Agerfalk, 2014; Corley and Gioia, 2011). Originality is related to the novelty of the analytical insight and the extent it adds to what has previously been known about the phenomenon. The argument for an original contribution is something a researcher generally pursues in the discussion section of a manuscript, where it is embedded in the wider body of literature. Theoretical contribution must be discussed in relation to existing theory. In MM-GTM, a novel contribution might be the addition of a recognition of how contextual factors, like a marginalized status, can interrupt conventional patterns of association.

Pragmatically oriented researchers have been at the forefront of advocating utility as a key indicator of quality. The pragmatic view is that the key issue is research produces conceptual and theoretical insight that prove useful (Bryant, 2009). This includes its scientific usefulness in generating new research as well as utility in practice (Corley and Gioia, 2011). In practice-oriented fields, like management, information systems, nursing and other medical fields, and education, includes the synergy produced in generating new ideas for evidence-based practice.

There are some unique challenges to gauging quality in MM-GTM, particularly about integration. The common practice of reporting on the qualitative and quantitative phases of a research project in separate publications can camouflage the significance of integration and complicate an attempt to assess its contribution and the breadth of its application. This complicates the practice of drawing conclusions about how integration occurred based on a single publication rather than the wider body of related work. This has implications for the treatment of dissonance or paradox as well. It is not uncommon to find, for example, that in complex projects reported over a series of inter-related publications, that authors end one article with a recognition of dissonance or paradox that cannot be explained readily, only to pick up a in a few years later.

Discussion

The goal of this encyclopedia entry has been to add to the argument for the credibility of MM-GTM by detailing a methodological rationale for the pairing. A methodology is a rationale for a research approach. This entry builds a rationale for using mixed methods and grounded theory in tandem by, first, identifying commonalities in their methodological assumptions, and, secondly, by highlighting some areas where each method can make a distinct contribution. Commonalities extend to the analytic logics, the way that grounded theory procedures can be adapted to accommodate diverse sources of data, and a shared set of contextual factors including the recognition of complexity and diverse perspectives. The overlap in key methodological features, supplemented by the distinct contribution of each method, is the basis of my argument that when pursued with a dialectical orientation MM-GTM can be considered a distinct methodology.

Fig. 1 summarizes key areas of overlap between the methodological framework of grounded theory and mixed methods. Three areas are highlighted: analytical logic, analytic procedures, and contextual factors.

Analytical logic is the first dimension where there is a shared compatibility between grounded theory and mixed methods. Items appearing in this box in the figure include abduction, the constant comparative methods, and adaptability to diverse philosophical paradigms. The second box in **Fig. 1** recognizes analytical procedures that can accommodate many types of approaches, including mixed methods. This applies to theoretical sampling, developing a coding system, and the role of the literature and other theories in serving as sensitizing concepts and to explain unexpected findings that emerge during the coding process. The third box in the figure refers to contextual factors that are a factor in both mixed methods and grounded theory. These include an aim to contribute analytical insight, the resilience to adapt to complex research questions and a dynamic research environment, the application largely in applied fields, and the likelihood that the inquiry engages many layers of a sociocultural environment.

The methodological assumptions of most approaches to grounded theory and mixed methods might differ in terms of the appreciation for the contribution of dissonance to generating theoretical insight, as well recognition of the role of verification and the treatment of exceptions. Very little space is awarded to these topics in most textbooks about grounded theory, particularly the first

Fig. 1 Overlap between the analytic logic and procedures of grounded theory and mixed methods.

and second generation to appear. The act of engaging or integrating findings from different sources of data that occurs in mixed methods allows for confirmation, but at the same time the disconnects generate topics for further exploration.

Design considerations

The complexity of the type of research questions tackled in both grounded theory and mixed methods is one explanation for the remarkable variety in the way MM-GTM has been implemented in practice. Integration is accomplished in diverse ways and for diverse purposes. A two phase, sequential approach where the phases are linked can be used for multiple purposes, including for instrument development. It is a design that readily accommodates the classic purpose of developing and testing a theoretical framework that is developed through grounded methods. An interactive design is used more frequently with MM-GTM in part as a response to the emergent quality demanded when findings from different sources are engaged. The credibility of each of these approaches is based on utility, originality, and providing documentation that traces the links between the data and the results reported.

Implications for practice

The inclusion of grounded theory as at least one phase in a mixed method project has implications for supporting the methodological dynamism of both approaches. For proponents of grounded theory, the more expansive umbrella of mixed methods may promote further initiatives to partner with feminist and transformative approaches by allowing researchers to be creative about what sources of data can be useful and to include research that occurs in naturalistic settings. A robust sample size allows for a wider range of sampling strategies than is often found in a grounded theory study. For researchers with an inclination toward mixed methods, a component that retains the integrity of grounded theory will ensure that a genuine qualitative phase that involves an exploratory component is not overlooked.

Directions for future research

For readers with methodological interests, there is a wide range of topics related to MM-GTM that have not been explored in any detail in the literature. This includes on the topics of the (a) variety of sampling approaches that might be accommodated in MM-GTM, (b) ways that grounded theory has been used to explore contradictory findings, (c) its role in elaborating an existing theory, (d) how the procedures can be modified with a secondary analysis of data that has been collected already. Developing standards of quality unique to MM-GTM is yet another area worthy of attention.

Glossary

Action research “A participatory process concerned with developing practical knowing in the pursuit of worthwhile human purposes. It seeks to bring together action and reflection, theory and practice, in participation with others, in the pursuit of practical solutions to issues of pressing concern to people” (Reason and Bradbury, 2008, p. 4)

Community-based participatory research “A systematic inquiry, with the collaboration of those affected by the issue being studied, for purposes of education and taking action or effecting change” (Green and Mercer, 2001, p. 1927)

Intersecting Intentional combination of two or more methodological approaches within a study design (Plano Clark and Ivankova, 2016)

Mixed methods research A research approach that emphasizes a meaningful integration of quantitative and qualitative approaches within a study or a program of inquiry with the purpose of generating more credible and persuasive conclusions about the research problem (Johnson et al., 2007; Tashakkori and Creswell, 2007)

Introduction

Mixed methods, action, and community-based participatory research approaches have long been applied in educational research. However, their meaningful intersection within a study provides enhanced opportunities to address complex educational problems by combining different methods and data sources, actively engaging stakeholders, and using cyclical approaches to finding solutions and bringing a positive change to a group or a community (Ivankova, 2015; Ivankova and Wingo, 2018; Johnson and Ivankova, 2019). A synergistic combination of multiple, action-oriented, and community-based methods allows researchers to explore the

course and outcomes of an issue, achieve more rigorous and transferable results to inform policy and practice, and deliver community-prioritized outcomes (DeJonckheere et al., 2019; Kim, 2014; O'Sullivan et al., 2017).

A methodological intersection occurs when two or more research approaches are intentionally joined within a study design. Plano Clark and Ivankova (2016) described intersecting mixed methods research (MMR) with other quantitative and qualitative research designs, methodological approaches, and theoretical frameworks by adding or embedding an MMR design to another approach, thus creating complex designs (Creswell and Plano Clark, 2018). Such intersection adds an MMR perspective to the research logic of another approach and design with consideration for their established research processes and practices.

Intersecting MMR with action research (AR) and community-based participatory research (CBPR) provides pragmatic opportunities for researchers to partner with stakeholders (e.g., administrators, faculty, staff, students, and parents) in education fields to identify and address areas in need of reform. Involving various stakeholders in research not only allows for a better understanding of their needs, but it can also promote solutions that are developed collaboratively rather than being imposed in a "top-down" approach, thereby enhancing the potential for stakeholder ownership (Ivankova, 2015). The systematic approach of the AR cycle also allows for iterative changes as needed. Ultimately, using MMR as part of AR and CBPR approaches can create policies or processes that can be sustained or revised in educational practice after the research has concluded (Ivankova and Wingo, 2018).

In the following sections we provide a brief overview of MMR, AR, and CBPR approaches. We discuss the common features of these approaches and the advantages of their meaningful intersection within a study context. We then introduce a mixed methods action research (MMAR) framework and its tools and discuss the procedural steps for applying the framework to design studies that intersect MMR with AR and CBPR.

Mixed methods research

Mixed methods researchers systematically collect quantitative and qualitative data and analyze them in an integrative manner in a single study (Tashakkori et al., 2021). An MMR approach can enhance the ability of researchers to conduct robust inquiry into a topic with complex research questions by using procedures that merge quantitative and qualitative data that have been collected concurrently or sequentially (Johnson and Onwuegbuzie, 2004). Integrating different types of data allows researchers to confirm knowledge using quantitative methods and generate knowledge using qualitative methods (Tashakkori et al., 2021). Researchers may choose to integrate quantitative and qualitative methods for various reasons, including exploring divergent views, enhancing credibility by confirming results, comparing and contrasting differences, expanding possibilities for discovery, and discovering pragmatic solutions to difficult problems in natural settings (Creswell and Plano Clark, 2018; Greene et al., 1989).

There are three core designs for MMR studies, depending on the timing or sequence of quantitative and qualitative data collection and analysis: (1) sequential QUAN → QUAL designs, in which quantitative data are first collected and analyzed, followed by qualitative data collection and analysis to expand on or explain results; (2) sequential QUAL → QUAN designs, in which qualitative data are first collected and analyzed, followed by quantitative data collection and analysis to generalize or confirm results; and (3) concurrent QUAN + QUAL designs, in which quantitative and qualitative data are collected and analyzed independently, with data integrated afterward to compare, contrast, and corroborate results (Creswell and Plano Clark, 2018; Plano Clark and Ivankova, 2016). These MMR designs may be used with other research approaches such as AR and CBPR, depending upon research questions and purposes (Ivankova, 2015). (See the cited sources for further description of these designs. You can also learn more about these designs by reading the chapter by Tajima and Feters in this volume.)

MMR has been increasingly popular among educators for decades. Creswell and Garrett (2008) traced a heightened interest in mixed methods research, in part, to the work of educators such as Jennifer Greene and colleagues in the late 1980s. As the use of MMR has increased, educators have also recognized the methodological advantages it provides in its ability to be combined with other research approaches such as AR and CBPR to address educational problems in practical ways (Ivankova and Wingo, 2018; Plano Clark and Ivankova, 2016).

Action research

AR seeks answers to questions that concern people in their groups or communities through a systematic approach that involves participants in all phases to develop "knowing in the pursuit of worthwhile human purposes" (Reason and Bradbury, 2008, p. 4). Due to its practical focus and collaborative nature, AR is often used as an umbrella term with reference to research that incorporates participatory and practice-oriented approaches (Duesbery and Twyman, 2020; Herr and Anderson, 2005). AR offers a process to address immediate needs and resolve problems in a specific setting in a more efficient way than traditional research (Greenwood and Levin, 2007). It also allows for inclusion of stakeholders as co-researchers in the research process, which can generate the potential for more effective solutions (McNiff and Whitehead, 2011). Rather than doing research on a group, researchers conduct the research together with group members, thereby promoting ownership of the research by the group participants (Brydon-Miller et al., 2003; McNiff and Whitehead, 2011). Participant empowerment is created throughout the research cycle, which ends with an intervention or action for improvement that also includes a mechanism to evaluate the intervention outcomes and their sustainability (Kemmis, 1982). By iteratively conducting research in this cyclical manner, educational researchers add to a body of knowledge that informs best practices for teaching in diverse settings (Hinchey, 2008; Stringer, 2021). AR also offers opportunities for collegial collaboration to accomplish goals that individual educators could not address alone (Sagor, 2000).

The process of AR allows researchers and stakeholders to combine theory with practice and action with reflection (Lewin, 1948; Reason and Bradbury, 2008). Kurt Lewin (1948) originally described AR as a four-step iterative process of reflecting, planning, acting, and observing, with a goal of solving real-life problems. Researchers begin by reflecting on possible solutions to a practical problem. They then gather facts about the problem (also known as *reconnaissance*) that allow them to plan how they might solve it. After implementing planned action steps to test their solution, they evaluate results, reflect on possible changes, and revise actions as needed. This cyclical process may be repeated continuously until positive changes are made to improve practice (Kemmis, 1982).

Community-based participatory research

CBPR is often viewed as a specific type of an AR approach that, as the term implies, is rooted in a community (Senge and Scharmer, 2001). The CBPR approach is often described as a “systematic inquiry, with the collaboration of those affected by the issue being studied, for purposes of education and taking action or effecting change” (Green and Mercer, 2001, p. 1927). Often used in public health and other healthcare fields, CBPR is based on the idea that understanding the culture and epistemology of a community is key to the inquiry process (DeJonckheere et al., 2019; Lucero et al., 2018).

To meet the needs of the community, CBPR incorporates a collaborative approach between researchers and community members at each stage of the research, seeking solutions to problems that impact everyday lives and empowering participants to enact social change (Israel et al., 2001; McNiff and Whitehead, 2011). This partnership can allow for perspectives of both “outsiders” and “insiders,” creating a trusting bond through shared power that can appeal to members of populations who might be skeptical about others proposing solutions to their problems (Lucero et al., 2018). Though CBPR can be “very complex, time-consuming, and resource intensive” (DeJonckheere et al., 2019, p. 497), it can give focus and depth to collaborative efforts to improve communities and create lasting impacts on the well-being of people who live in them. In the following section, we describe the common features of MMR, AR, and CBPR approaches and the advantages of intersecting them to address real-life educational problems.

Common features of MMR, AR and CBPR approaches

A number of shared conceptual, philosophical, and procedural characteristics make a meaningful intersection of MMR with AR and CBPR approaches possible and advantageous (Ivankova, 2015; Ivankova and Wingo, 2018; Ivankova and Johnson, 2021).

Conceptual characteristics

MMR, AR, and CBPR aim at providing a comprehensive exploration of the studied issue. MMR integrates quantitative and qualitative methods, data, and results, thus increasing the breadth and depth of understanding (Johnson et al., 2007). AR and CBPR rely on cyclical spirals of critical action and reflection with stakeholder engagement to design robust action plans grounded in more weighted solutions (McKernan, 1988).

Addressing complex issues requires dialectical thinking (Greene, 2007). MMR addresses a range of exploratory and confirmatory questions within a single study by creatively integrating available data and diverse perspectives (Tashakkori et al., 2021). The dialectical nature of AR and CBPR is reflected through the iterations of reflection, planning, acting, and observing (Lewin, 1948), while incorporating diverse stakeholders’ viewpoints in each stage of the research spiral.

Reflection is an important component of any research process. Due to a multi-strand nature of MMR, designing and conducting an MMR study requires reflection about a range of theoretical and procedural issues related to the research focus and design of each study phase and integration of the quantitative and qualitative components. Reflection is an inherent component of AR and CBPR as researchers critically reflect over the assessment of the identified problem, make decisions about the required intervention, and consider the action outcomes to inform further action steps (Mills, 2011).

MMR, AR, and CBPR are highly collaborative in nature. The breadth and scope of mixed methods studies requires different research strategies calling for different forms of expertise and a collaborative team approach (Shulha and Wilson, 2003). Collaboration is one of the principles of AR and CBPR, because it requires collegial interactions, active participation, and joint problem-solving by all stakeholders and at all stages in the study process (McNiff and Whitehead, 2011).

Philosophical characteristics

Pragmatism that rejects “either-or” thinking and views knowledge as both a process and a product of empirical investigation (Johnson and Gray, 2010) provides a major philosophical foundation for MMR, AR, and CBPR. Pragmatism rejects the quantitative and qualitative incompatibility thesis and helps justify the integration of quantitative and qualitative methods within an MMR study. The need to design and implement action plans that would provide effective solutions of practical problems also requires a “what works” approach in AR and CBPR studies.

The three approaches are often seen as value laden and applying a transformative or advocacy lens to advocate for social justice. Moreover, a transformative mixed methods approach is often viewed as embedded in participatory AR (Mertens et al., 2010), because it encourages community engagement to produce knowledge that reflects the power and social relationships in the society. AR and CBPR approaches are grounded in the practice of co-creating knowledge and empowering participants for change through an iterative process of action and learning (Herr and Anderson, 2005).

Balancing insider-outsider perspectives is common in MMR, AR, and CBPR. In MMR, researchers take an outsider observer role when they collect and analyze numeric or etic data. Alternatively, they take an insider role when they qualitatively explore and interpret perspectives and experiences of individuals, thus producing emic data. AR and CBPR often involve multiple stakeholders and collaborative partnerships, which helps preserve both the insider and outsider perspectives in the inquiry process (Herr and Anderson, 2005).

Procedural characteristics

MMR, AR, and CBPR are designed and conducted following a set of systematic procedures or steps, moving from the identification of the research problem and formulation of research questions to data collection, analysis, interpretation, and evaluation. Both quantitative and qualitative data are required when there is a need to address confirmatory and exploratory questions within a single MMR study. AR and CBPR traditionally rely on multiple sources of quantitative and qualitative evidence to find comprehensive solutions to complex practical issues (Koshy et al., 2011).

The three approaches follow a cyclical process consisting of clearly defined study phases. An MMR study often consists of multiple quantitative and qualitative strands that are implemented sequentially in an iterative manner, with one study strand informing another strand (Tashakkori et al., 2021). In AR and CBPR studies, one step leads to another and is repeated multiple times, forming a research spiral aimed to generate well-informed solutions (Herr and Anderson, 2005).

Advantages of intersecting MMR with AR and CBPR approaches in education

As we have discussed, intersecting MMR with AR and CBPR allows researchers to address practical issues in systematic ways that enhance the translation of research into practice. Table 1 outlines the advantages of combining these approaches in more detail. Studies intersecting MMR with AR and CBPR may be found across diverse fields of education, including elementary education (Kostos and Shin, 2010; Owen and Davies, 2020), secondary education (Bogar et al., 2017; Ollis and Harrison, 2016; O'Sullivan et al., 2017; Snyder et al., 2016; Zocher and Hougham, 2020) and higher education (Cabaroglu, 2014; Sampson, 2010; Tsai and Jao, 2020).

One advantage to using MMR with AR in educational studies is that it offers researchers the opportunity to better understand how the unique culture of a school may influence the implementation of pedagogy. For instance, one Montessori school in Western Australia that served children aged 18 months to 15 years used MMR in an AR project to determine how to introduce digital learning technologies to students without compromising the school's pedagogical and philosophical values (Owen and Davies, 2020). Researchers may also use MMR in AR projects to determine whether accepted educational practices will be effective with specific groups of students. Tsai and Jao (2020) conducted a study to examine how team-based learning (TBL) strategies influenced student learning and teacher course design in one radiologic technology course at a junior college in Taiwan. Quantitative data included student performance scores, while qualitative data included answers from open-ended surveys of students and a series of three teacher interviews (Tsai and Jao, 2020).

Table 1 Advantages of intersecting MMR with AR and CBPR.

Addressing a practical issue in a systematic and dialectic way through

- A combination of theory with practice and action with reflection
- Exploration of diverse views of stakeholders across a community
- Comprehensive assessment of a problem from different perspectives
- Development of a reliable and valid action/intervention plan tailored to diverse needs
- Rigorous evaluation of the action/intervention
- Opportunities for iterative changes if needed
- Credible and valid conclusions about action/intervention outcomes
- An evidence-based approach to action/intervention monitoring
- Enhanced action/intervention sustainability

Enhancing translation of research into practice by

- Cultivating an understanding of community culture and epistemology
- Enhancing stakeholder engagement at every phase in an action research cycle
- Creating a sense of ownership and empowerment among stakeholders
- Building bonds of trust among community members to enhance social justice
- Optimizing action/intervention outcomes
- Illuminating and assessing change over time
- Empowering young people to become change agents
- Supporting effectiveness of change action
- Promoting sustainability of meaningful change
- Enhancing transferability of action/intervention results to other contexts and community settings

Adapted from Ivankova and Wingo (2018) with permission of Sage Publishing

Intersecting MMR with CBPR can also be especially appropriate for educational research, as the involvement of stakeholders in CBPR research designs enhances opportunities to address advocacy issues for marginalized groups and promotes inclusion of multiple voices. For example, [Zocher and Hougham \(2020\)](#) used MMR in a CBPR study in an urban high school that explored how two different approaches to experiential projects enhanced students' environmental literacy and their abilities to advocate for changes in the community to overcome environmental oppression. Participants included students, staff, and alumni of the school; data were collected through observations, surveys, interviews, and document reviews ([Zocher and Hougham, 2020](#)). Another CBPR study in environmental education ([Bogar et al., 2017](#)) used MMR to assess urban youth's knowledge of and attitudes toward lead poisoning and other environmental health concerns by establishing a research team including a doctoral candidate, an education coordinator, and a group of young people ages 10–18 at a local youth organization.

In fact, a specific type of CBPR for educators to consider is “youth-led participatory action research” (YPAR), which empowers young people by engaging them at all stages of research to identify and solve problems that affect them ([Martinez et al., 2020](#); [Suleiman et al., 2021](#)). YPAR can be especially effective in helping young people develop leadership skills and providing opportunities for diverse and marginalized youth to address social justice issues ([Akorn, 2011](#); [Suleiman et al., 2021](#)).

Challenges of intersecting MMR with AR and CBPR approaches in education

The characteristics that make intersections of MMR with AR and CBPR so effective in educational research can also be challenging to implement. By its very nature, collaboration can be difficult, as it requires all stakeholders to be engaged in research tasks and appropriately responsive to feedback from other team members. Engaging stakeholders as co-researchers in MMR studies can be particularly challenging due to the complexity of mixed methods designs and the need for expertise in quantitative and qualitative data collection and analysis. Moreover, it requires a collaborative effort between researchers and community partners to construct joint meanings of the mixed methods data ([Shulha and Wilson, 2003](#)). Fostering co-learning and capacity building among all partners to enable a meaningful intersection of MMR with AR and CBPR is one of the principles of effective community-based action research studies ([Israel et al., 2001](#)).

Issues around trust and shared power among team members can also cause a breakdown in research progress ([Herr and Anderson, 2005](#)). The need to reflect takes time and patience, and the cyclical process of research designs that combine MMR with AR and CBPR may require extensive time and resources. Since the cyclical nature of MMAR projects is viewed as being “a continual improvement process” ([Hinchey, 2008](#), p. 5), educators are encouraged to take a reflective stance and critically evaluate the results from each cycle to determine whether the desired improvements have occurred or can be feasible.

Studies that are conducted with an advocacy lens almost inevitably face stakeholder discomfort or even power struggles, as they often call for dramatic changes within community culture. Considering contextual factors and carefully adapting effective interventions to specific community needs can help mitigate power structures and ensure the achieved results are tailored to the cultural practices and fit the worldviews of the target group ([Wingood and DiClemente, 2008](#)). Qualitative research approaches as part of a larger MMR study can help solicit stakeholders' views and their first-hand experiences with the issue to compare them with quantitative assessments of the action/intervention outcomes.

The challenges in combining MMR with AR and CBPR must be acknowledged as part of initial steps in study design. Collaboration among research teams can be strengthened if all members resolve to participate fully in the research process, communicate consistently, and provide honest and timely feedback. Setting expectations about flexible timelines may prevent unreasonable project deadlines and allow time for reflection and critical evaluation. Finally, for the project to drive meaningful change, research teams must understand the complexity of potential issues and commit to persevering despite obstacles they may encounter.

Methodological considerations of intersecting MMR with AR and CBPR

Levels of intersection

Ten shared characteristics of MMR, AR, and CBPR discussed above suggest an explicit blending of conceptual, philosophical, and methodological premises when intersecting MMR with AR and CBPR. Therefore, a meaningful intersection of MMR with AR and CBPR requires careful considerations at several levels, including epistemological, axiological, and methodological ([Ivankova and Johnson, 2021](#)).

At the epistemological level, researchers make decisions about how to generate the types of knowledge about the studied problem by capitalizing on the advantages of MMR, AR, and CBPR. For example, the decisions relate to the type of research questions and the integration of the quantitative and qualitative approaches to address these questions, the inclusion of stakeholders' perspectives and participants' voices, and working with communities to understand their needs and to identify meaningful solutions to a practical problem from their perspective ([Bradbury, 2015](#)). At the axiological level, researchers consider the values associated with the epistemological and methodological choices during the research process. When using MMR, researchers allow the qualitative and quantitative components to interact within a study by bringing stakeholder values into a dialog and interpretation of the quantitative results ([Greene, 2007](#); [Johnson, 2017](#)). AR and CBPR approaches promote collaborative and empowering research activities that encourage researcher reflexivity and power sharing between the researcher and researched ([Israel et al., 2001](#); [Kral and Allen, 2015](#)).

At the methodological level, MMR, AR, and CBPR intersect when researchers combine these approaches within a methodological framework to inform the planning, design, and implementation of MMAR/CBPR studies. The MMAR framework was first developed to provide a systematic approach to support decision-making when combining MMR with AR (Ivankova, 2015; Ivankova and Wingo, 2018). It was also applied to promote patient-centered research (Ivankova, 2017) and as a means of enhancing translation of knowledge into practice (Ivankova et al., 2018). In the following sections we describe the MMAR framework and its practical tool, the MMAR study process model, which aims to help researchers translate the MMAR framework into a practical application.

MMAR framework

The MMAR methodological framework depicted in Fig. 1 conceptually follows the cycle of AR methodological steps outlined by Lewin (1948) and captures the synergetic combination of the two approaches by intersecting MMR with AR in every step. The framework includes six iterative phases (diagnosing, reconnaissance, planning, acting, evaluation, monitoring) during which conceptual, procedural, and inferential aspects of MMR inform the steps in the AR cycle in different ways. Full MMR studies consisting of conceptualization, quantitative and qualitative data collection and analysis, and developing integrated inferences are conducted in the reconnaissance and evaluation phases using one of the core MMR designs (see Creswell and Plano Clark, 2018). MMR inferences from these phases inform the rest of the steps in the AR cycle. Consistent with the participatory principles of AR, each phase in the framework involves collaboration with study participants and key stakeholders, whose active involvement can provide support for the project's success in the community. In Fig. 1, solid arrows indicate the sequence of the phases in the AR process, while dashed arrows show other possible iterations of the research activities within an AR cycle.

During the diagnosing phase, the problem that requires solution in the workplace or community setting is identified, and the advantages of addressing it by using both MMR and AR are explored in collaboration with community partners. In the reconnaissance phase, an MMR study is conducted to generate more context-specific understanding of the community's needs and to help define the outcomes that require improvement. The MMR inferences from the reconnaissance phase are then used to plan a data-driven intervention and to inform its implementation during the acting phase. During the evaluation phase, an MMR design informs the collection, analysis, and integration of the quantitative and qualitative data to assess the intervention outcomes and to identify further steps. The MMR inferences drawn from the evaluation phase inform the intervention monitoring to help achieve a satisfactory resolution of the problem with the input of stakeholders and community. Monitoring helps identify whether the problem is successfully resolved or requires further diagnosis, reconnaissance, or re-planning of the intervention, which is shown by dashed arrows in Fig. 1.

Fig. 1 Mixed methods action research framework. MMR: mixed methods research. Adapted from Ivankova (2015) with permission of Sage Publishing.

MMAR study process model

The MMAR study process model is a visual tool that helps apply the MMAR framework to conceptualize, design, and implement a study that intersects MMR with AR and CBPR to address a practical problem (Ivankova, 2015, 2017). The model unfolds the MMAR framework into an MMAR process to assist researchers with identifying the procedural steps within each phase of the AR cycle, using integrated MMR data and inferences, and soliciting the input of stakeholders and community partners while maintaining a focus on the overarching issue. By explicitly presenting methodological details for each phase, the model provides a roadmap for researchers to engage the key stakeholders in developing a plan to improve, monitor, and further adapt an effective intervention.

In the following sections, we illustrate the application of the MMAR framework and the MMAR study process model in education using three studies that intersected MMR with AR and CBPR approaches in different phases (reconnaissance, evaluation, and both phases) in the AR cycle. We briefly describe the study and the authors' rationale for intersecting MMR with AR and CBPR and discuss the MMAR process using diagrams depicting specific MMR and AR procedures during each phase. Solid arrows show the flow of the activities that were implemented in the study and reported in the paper, whereas dashed arrows suggest further steps related to monitoring of the implemented intervention.

Example of the MMAR process with MMR in the reconnaissance phase

Ivankova and Wingo (2018) described the MMAR process in Ollis and Harrison's (2016) AR study that used MMR in the reconnaissance phase to explore capacity for building a comprehensive sexuality education program using the health promoting school framework (HPS) in a five-campus, year 1–12 college in Victoria, Australia. The researchers chose AR because the spiral of "self-reflection, planning, implementation, monitoring and reflection on the data gathered, replanning in the light of reflection, and entering a new phase of action and monitoring, fitted with the aims of whole school change" (Ollis and Harrison, 2016, p. 141). Using MMR in the reconnaissance phase allowed researchers to employ quantitative methods to survey students, parents, teachers, and other key stakeholders to examine their attitudes and beliefs, while also using qualitative methods (participant observation and semi-structured interviews) to explore school culture and determine staff readiness to implement the program. Fig. 2 shows the MMAR process based on Ollis and Harrison's (2016) study.

The researchers used a concurrent (QUAN + QUAL) mixed methods design to determine critical factors to develop, implement, and potentially sustain the program. They surveyed year 9 students ($n = 34$), teachers ($n = 101$), parents and caregivers (no number reported), students at various levels (no number reported), and participants in professional development workshops ($n = 25$) to collect quantitative data. They also conducted semi-structured interviews with working group members and observations of working group meetings, teacher professional development and planning sessions, parent and community forums, and other school events. The researchers integrated these quantitative and qualitative data to plan and articulate the key aspects of the program (e.g., vision, strategic goals, program alignment, and stakeholder roles). They also implemented a professional development workshop series for teachers and conducted parent and community forums to create a support system for the program. The sexuality education program was successfully implemented, and although researchers did not report on the program evaluation and monitoring, which is marked by dashed arrows in Fig. 2, they emphasized that program assessment and sustainability would need to be researched in the future using quantitative and qualitative methods to better understand students' experiences and teachers' capacity.

Example of the MMAR process with MMR in the evaluation phase

Kostos and Shin (2010) applied the MMAR process to investigate the impact of math journaling instruction on second-grade students' communication of mathematical thinking by using MMR in the evaluation phase (Ivankova, 2015). An AR approach was chosen because it enabled the teacher-researcher "to utilize the insight that can only be obtained as an insider to the setting" (p. 226) and to capture the students' thinking process more closely. MMR was used in the evaluation phase "to provide a more in-depth look at how the students communicated their mathematical thinking when using math journals" (p. 226).

The study was conducted in a second grade mixed-ability classroom in a suburban school in Chicago. Using a concurrent (QUAN + QUAL) mixed methods design, the data were collected from 16 students, eight girls and eight boys, to assess whether a 5-week math journaling intervention had improved the second graders' communication of mathematical thinking. The quantitative data consisted of an identical math assessment administered to students before and after the intervention using the Illinois State Board of Education Mathematics Scoring Rubric. The qualitative data included students' math journal entries, interviews with eight randomly selected students, and the teacher-researcher's reflective journal. Fig. 3 shows the MMAR process based on Kostos and Shin's (2010) study.

Comparison of students' pre- and post-test scores, qualitative themes from students' math journals and interviews, and teachers' reflections allowed the researchers to obtain corroborating evidence that the use of math journals positively influenced the students' communication of mathematical thinking and use of math vocabulary. Based on these findings, the teacher-researcher decided to more systematically incorporate math journaling in daily math lessons. Solid arrows in Fig. 3 show the actual flow of the research activities in the study, while dashed arrows highlight potential future activities related to further evaluation and monitoring of the math journaling instruction or the need to conduct more literature review and students' needs assessment to inform effective changes in the instructional approach.

Fig. 2 MMAR process based on Ollis and Harrison's (2016) study. Reprinted from Ivankova and Wingo (2018) with permission of Sage Publishing.

Fig. 3 MMAR process based on Kostos and Shin's (2010) study.

Example of the MMAR process with MMR in both reconnaissance and evaluation phases

Sampson (2010) applied the MMAR process in a semester-long study that used students' feedback to guide the choice of a lesson style in a college level class in which English was the language of instruction (Ivankova, 2015). AR was chosen for its participatory and collaborative nature and the fact that "the subjective views of learners are of most importance in enacting change" (Sampson, 2010, p. 286). MMR was used in both reconnaissance and evaluating phases for triangulation purposes to "most effectively inform the change-action" (p. 286).

Twenty-two first-year students in two Interpersonal Communication classes from a women's university in Japan took part in the study. During the reconnaissance phase, a concurrent (QUAN + QUAL) mixed methods design was used for collecting and analyzing the data, which consisted of a quantitative survey (the Lesson Style Questionnaire) and a narrative exercise (the Language Learning Autobiography), to identify students' preferred lesson styles. The integrated results from the analysis of the two data sets were used to develop task-based oriented lessons (TBL) to introduce more opportunities for using the English language in the classroom setting. The researcher employed a different sequential (QUAL → QUAN) mixed methods design to evaluate the instructional intervention. First, qualitative reflective narratives about the learning activities during each class from the students' journals were analyzed for themes to inform the development of the quantitative Learning Experience Questionnaire tailored to students' needs. The students completed the questionnaire at the end of the course. The quantitative results were then compared with the qualitative themes from the learning journal entries to obtain more informed conclusions about the effectiveness of the new lesson style and students' perceptions of their speaking and communication abilities in English. Fig. 4 shows the MMAR process based on Sampson's (2010) study.

Solid arrows in Fig. 4 show the actual flow of the research activities in the study, while dashed arrows suggest potential further evaluation and monitoring of the TBL intervention with the possibility for conducting more assessment of new students' preferences for EFL lesson style instruction. It is likely that the researcher will return to the reconnaissance phase when teaching another course to identify the lesson style preferences of a different cohort of Japanese college students. This cohort may be different from the one used in the study, and the previously developed intervention consisting of task-based lessons may not meet the needs of these students.

Applying MMAR framework to design studies that intersect MMR with AR and CBPR

The MMAR framework provides a methodological foundation for designing studies that intersect MMR with AR and CBPR approaches. The following procedural steps that align with the MMAR framework help translate the application of the framework in research practice (Ivankova and Johnson, 2021; Johnson and Ivankova, 2019). Table 2 summarizes the steps and their alignment with the phases in the MMAR framework.

Step 1: understanding the problem and community needs

During the first step, researchers collaborate with stakeholders to identify the problem that requires improvement using an MMAR approach and to understand what has been already done to address the issue. The diagnosing phase can also involve exploration of the previous activities and initial needs assessment by iteratively cycling through the diagnosing and reconnaissance phases. In Ollis and Harrison's (2016) study, researchers engaged all critical stakeholders including students, teachers, parents, and community members to help them understand how to design and implement a school comprehensive sexuality education program. Sampson (2010) relied on students' past English learning experiences and hopes for college speaking classes to motivate students to practice English in a classroom. Kostos and Shin (2010) conducted an extensive literature review and students' baseline math assessment to help students improve their math communication skills.

Step 2: aligning information with the phases in the MMAR framework

Based on the information about a practical problem gathered during Step 1 (diagnosing phase), researchers identify the point of entry into the AR cycle, which can be either developing an intervention tailored to stakeholders' and community needs or starting with the evaluation of the existing intervention or program. The entry point depends on whether this is a newly diagnosed issue or an ongoing problem with some actions already taken toward its resolution within the phases of the AR cycle. Using the MMAR framework, researchers map the activities to the MMAR process model to guide the research process and communicate the planned research activities to stakeholders for their support and input. In Ollis and Harrison's (2016) and Sampson's (2010) studies, researchers started with the reconnaissance phase because they wanted first to explore stakeholders' perceptions of and experiences with the problem before developing a plan for action. Included were not only students and teachers who would be directly affected by a sexuality education program, but also parents and other key stakeholders, whose perspectives were crucial for understanding the program's vision, mission, and potential resources. In Kostos and Shin's (2010) study, researchers started with implementing and evaluating the math journaling intervention because it was a reported effective pedagogical approach.

Fig. 4 MMAR process based on Sampson's (2010) study.

Table 2 Procedural steps for applying the MMAR framework to design studies that intersect MMR with AR and CBPR.

<i>Procedural steps</i>	<i>Alignment with the MMAR framework</i>
Step 1. Understanding the problem and community needs.	- Identifying the problem area that requires improvement using an MMAR approach. - Conducting needs assessment by iteratively cycling through the diagnosing and reconnaissance phases.
Step 2. Aligning information with the phases in the MMAR framework.	- Identifying the entry into the AR cycle depending on the state of the problem and community needs. - Framing prior activities within the phases of the AR cycle.
Step 3. Orienting to the MMAR study process and building community research capacity.	Unfolding the steps in the MMAR process and identifying preceding and subsequent phases in the MMAR study cycle.
Step 4. Designing reconnaissance and/or evaluation phases of the MMAR study.	Designing and implementing reconnaissance and/or evaluation phases using a MMR design to inform the development of the action/intervention plan and/or to evaluate intervention effectiveness and promote sustainability.
Step 5. Identifying the next steps in the MMAR study process.	Using the meta-inferences and deliverables that have been created during the reconnaissance and/or evaluation phases to identify the need for potential iterations between and among the phases.

MMR: mixed methods research; AR: action research; MMAR: mixed methods action research.

Adapted from [Ivankova and Johnson \(2021\)](#) with permission of Routledge.

Step 3: orienting to the MMAR study process and building community research capacity

Capitalizing on the collaborative nature of the AR and CBPR approaches, the next step involves engaging stakeholders and community partners with the research process in a meaningful and practical way. This includes educating all involved parties about the MMAR process while seeking their input into the phases of the MMAR study cycle and the components of the intervention plan. Using an MMAR study process model that visually depicts the evolving research activities makes it easier for researchers to work with community partners to reveal additional gaps in knowledge. In [Ollis and Harrison's \(2016\)](#) study, researchers worked with multiple community partners to identify the supporting factors for developing, implementing, and sustaining a sexuality education program. Training opportunities were provided to teachers, parents, and community members to help establish the infrastructure for the program implementation. [Sampson \(2010\)](#) engaged his students as co-researchers in developing the TBL instruction building on their previous language learning experiences. In [Kostos and Shin's \(2010\)](#) study, second graders actively participated in the research activities as part of their classroom duties.

Step 4: designing reconnaissance and/or evaluation phases of the MMAR study

During this step researchers design and conduct MMR studies in the reconnaissance and/or evaluation phases relying on available data, resources, and stakeholder participation to inform the subsequent phases in the MMAR study cycle. Decisions involve a choice of the MMR design, the timing of quantitative and qualitative data collection and analysis, and the planned outcomes from each phase. MMR inferences or integrated study conclusions ([Tashakkori et al., 2021](#)) are generated to provide information for intervention development, implementation, or monitoring. In [Ollis and Harrison's \(2016\)](#) study, the integrated results from the concurrent collection and analysis of the qualitative interviews with the members of the program's working group and quantitative surveys of teachers, students, and parents allowed researchers to better determine vision, strategic goals, program alignment, and roles of various stakeholders in the program implementation. In [Kostos and Shin's \(2010\)](#) study, the integrated quantitative and qualitative findings from students' math assessments, journals, and interviews provided evidence that math journaling enhanced student learning. In [Sampson's \(2010\)](#) study, the use of different MMR designs in the reconnaissance (concurrent) and evaluation (sequential) phases provided a comprehensive approach to developing and evaluating an instructional intervention resulting in improved language learning outcomes.

Step 5: identifying the next steps in the MMAR study process

Given the cyclical and iterative nature of an MMAR study that continues following the phases in the MMAR framework until the problem is positively resolved, the phases are repeated based on the outcomes from each phase. Researchers use the meta-inferences from the reconnaissance and/or evaluation phases to identify the next steps and potential iterations between and among the phases in collaboration with stakeholders. It took several years and multiple data sources to plan, develop, and implement the sexuality education program in [Ollis and Harrison's \(2016\)](#) study. The cyclical nature of the MMAR approach and continued capacity building "fitted with the aims of whole school change" (p. 141). In [Kostos and Shin's \(2010\)](#) study, although not explicitly stated, more evaluation of math teaching and learning strategies for second grade students would be conducted to inform potential revisions or adjustments in the intervention. In [Sampson's \(2010\)](#) study, it is likely that the researcher will return to the

reconnaissance phase when teaching another course to identify the lesson style preferences of a different cohort of Japanese college students. A new cohort may be different from the one used in the study, and the previously developed intervention may not meet these students' needs.

Conclusion

Educators often face challenges that require them to collaborate with diverse stakeholders to identify problems, design and implement solutions, and evaluate outcomes. Developing and evaluating educational interventions grounded in a systematic and comprehensive MMR assessment of the problem in collaboration with stakeholders helps to more efficiently reveal critical areas for action and find solutions that are meaningful and acceptable to all affected by the issue. Informed by the MMAR framework, the cyclical MMAR study process model provides a logical yet flexible structure to guide problem-solving, while the participatory nature of AR and CBPR approaches allows for the inclusion of multiple voices to advocate for stakeholder groups. Intersecting MMR with AR and CBPR approaches can provide robust, data-driven evidence to support decisions, reveal new insights, and drive meaningful and sustainable change in educational practice.

Mixed methods research and evaluation are commonly used within the social sciences. Qualitative Comparative Analysis (QCA) is a method and analytic approach that can be used within a larger mixed methods evaluation. As a method, it entails a process and series of decisions based on theory, empirical information, and feasibility; as an analytic approach, it is used to identify complex patterns in data using non-statistical mathematical techniques (Schneider and Wagemann, 2012; Kahwati and Kane, 2020). In this encyclopedia chapter, we provide a brief introduction to the method, offer examples of how it has been used, and discuss considerations for its use.

History of QCA development

QCA was developed by a sociologist, Dr. Charles Ragin, in the early 1980s (Ragin, 1999, 2000, 2006). Ragin recognized the need for an approach within the social sciences that could assess complex causal relationships that are best formulated in terms of set relationships, rather than statistical relationships. For example, hypothesizing that school programs that provide disadvantaged students with mentors leads to increases in high school graduation rates can be expressed in terms of a set relationship. Stated as a set relationship, school programs with mentors are a subset of all schools with increased graduation rates. Similarly, he noted the need to define a systematic method to identify causally relevant commonalities across cases, which is a feature of cross-case comparison within qualitative methods (Ragin, 2000). Finally, because Ragin worked primarily in the comparative historical sociology and political science arena, the size of the samples available to researchers in this field were inherently restricted (e.g., numbers of countries, jurisdictions, events), which limited the use of traditional statistical methods. Since its initial development, many other social scientists have contributed to the further development of QCA methods. Increasing examples of its use in empirical research across a variety of academic fields including social and environmental policy research (Verma, 2012; Ide, 2015), management research (Fiss, 2011; Frambach et al., 2016), education (Kintz et al., 2015; Coburn et al., 2012), and healthcare and public health services research (Kahwati et al., 2016a, b; Kane et al., 2017; Thygeson et al., 2012) is also evident.

Method overview

QCA has several defining features (Schneider and Wagemann, 2012; Kahwati and Kane, 2020; Ragin, 2000, 2008). First, it entails a case-based approach, which means that cases are treated holistically and not deconstructed into component variables for analysis. Treating a case holistically means examining the complex interplay of factors that can lead to an outcome, rather than quantifying the degree to which any single variable is correlated with an outcome. Second, the method can integrate qualitative and quantitative data, though ultimately all data is transformed (or calibrated in QCA terms) into numeric values for analysis. Third, QCA involves using formal logic and set theory, a branch of mathematics that entails the examination of the relationships between sets, for cross-case comparison to identify set relationships between explanatory factors (*conditions* in QCA terminology) and outcomes. The two types of set relationships that QCA can identify if they are present in the data are *necessity* and *sufficiency*. A necessary condition (or combination of conditions) must be present (or present at a high level) for an outcome to occur but does not guarantee the outcome occurs. A sufficient condition indicates that where that condition (or combination of conditions) is present, the outcome is also present (Ragin, 2000, 2008). Finally, QCA is based on an underlying assumption of causal complexity within the phenomenon being studied. Three concepts characterize causal complexity: equifinality, conjunctural causation, and asymmetrical causation. These underlying assumptions are what distinguish QCA from probabilistic methods of testing for associations. **Box 1** illustrates these concepts using cookie recipes.

Box 1 Causal complexity explained: pathways to a good chocolate chip cookie (Kahwati and Kane, 2020)

The chocolate chip cookie, a favorite of many people was invented by American Chefs named Ruth Graves Wakefield and Sue Brides in 1938. It is made from flour, butter, white and brown sugar, vanilla, with little chips of chocolate mixed in. When preparing these cookies, both home and professional bakers want the desirable outcome of a “good tasting chocolate chip cookie.”

Many different chocolate chip cookie recipes are available. If one were to do an internet search and collect all the chocolate chip cookie recipes and then create a single recipe by taking the average of all the flour called for across the recipes, the average of all the butter called for, the average of all the sugars, and so on for all of the other ingredients, one could produce a single recipe, which would be a *unifinal* recipe. A cookie produced from this *unifinal* recipe represents the effect of using the average amounts of ingredients from across all of the various recipes. Some of the contributing recipes might not have been that good, and some of them might have been great. With the *unifinal* recipe, one has only that single recipe to use. Back to research for a moment, the probabilistic methods we use are based on assumptions of *unifinality*. In reality, many different recipes can result in a “good-tasting chocolate chip cookie;” there is not just one, single recipe that will lead to this outcome. This is *equifinality*, the concept that more than one combination of factors (or ingredients) can lead to an outcome.

For *conjunctural causation*, the cookie ingredients lend insight. Many recipes for a good-tasting cookie call for the use of both baking soda (bicarbonate) and baking powder (bicarbonate plus an acid like cream of tartar). A recipe with only baking powder leads to a cookie that is too tangy (acidic) and that is too pale. A recipe with only baking soda does not rise well and has a bitter taste, but a recipe with both baking soda and baking powder (in conjunction) leads to a chemical reaction that provides the perfect lift, the right amount of browning, and a balance between acid and base for a good-tasting cookie. This is a *conjunctural causation*: a factor may not be causally related to an outcome on its own but only related to the outcome in the presence of another factor.

Finally, the fat in the cookie recipe is useful for illustrating *asymmetrical causation*. All good-tasting cookies have some fat in the recipe. Using real butter leads to good-tasting cookies, but not using butter does not necessarily mean a cookie will not taste good. Many cookie recipes that result in a “good-tasting chocolate chip cookie” use margarine, shortening, or some alternative fat. This is *asymmetric causation*; even though the presence of an explanatory factor produces the outcome, one cannot assume that the absence of the factor leads to the *non-occurrence* of the outcome.

QCA is particularly well-suited to addressing configural research questions. Configural research questions are questions formulated to ask about the relationship of combinations of factors (i.e., conditions) with an outcome. A configural research question asks, “What combinations of conditions or factors are necessary or sufficient for an outcome?” For example, “Which combinations of new teacher training, supports, and policies are found among school districts with high rates of teacher retention?” All three concepts related to causal complexity are represented by configural questions.

QCA within mixed methods evaluation

Mixed methods study designs or evaluations include both qualitative and quantitative methods to complement each other for addressing specific research questions (Curry and Nunez-Smith, 2015; Plano Clark and Ivankova, 2016). Various mixed methods designs exist, and the specific design investigators select depends on the research questions. Because QCA is not a purely qualitative or quantitative method, it may not be traditionally included in the arsenal of methods to consider as part of a mixed methods design. However, it can be a useful approach to include in a mixed methods design when one of more of the research aims include configural research questions (Kahwati and Kane, 2020).

QCA can be used in such designs by (1) integrating the qualitative and quantitative data into a single analysis, (2) providing an analytic step between sequenced data collection, or by (3) supplementing a secondary point of integration between the qualitative and quantitative methods (Kahwati and Kane, 2020). Findings from the qualitative strand of a mixed methods study (e.g., case studies) can also be used to enhance the findings of a QCA by offering rich details about how the patterns identified by the QCA are exemplified in the cases. First, when developing conditions or an outcome for a QCA in a mixed methods study, one can transform qualitative data into numeric data; additionally, one can also apply substantive knowledge to measured quantitative variables. Second, QCA can be a part of a mixed methods study and, if needed, be used at multiple points in a mixed methods study. For example, a researcher could develop conditions based on qualitative data and use QCA to create typologies of cases that could be included in a statistical model. Alternately, the quantitative data could also be transformed into conditions for typology development through QCA, and then the researcher could use the different typologies to purposively select cases for qualitative data collection. Third, QCA can offer an additional analysis to support the qualitative and quantitative strands; a mixed methods study could have a research question with a configural aim, which would rely on QCA and merged or embedded integration.

Examples from the field

In this section we offer high-level summaries of published examples of QCA used to address configural research questions in the field of education research and closely related social science fields. These examples illustrate the use of QCA with different units of analysis as cases: countries, organizations, schools. Cases can also be individuals or defined based on discrete events (e.g., mass school shootings, labor strikes) or conceptually-bounded phenomenon (e.g., legislation, guidelines, programs, or standards).

- Assmann and colleagues used QCA to explore combinations of country-specific conditions related to differing rates of young people (age 15 to 29) not engaged in the labor force or in the education system (NEETs) (Assmann and Broschinski, 2021). The authors ran several models based on the reason that the young people were not engaged (this chapter provides one model as an example). Model 1 examined the factors related to high rates of NEETs who are actively seeking employment but cannot find work.
 - *Configural Question*: What combinations of country-specific conditions are necessary or sufficient for having high rates of NEETs who are actively seeking employment but cannot find work?
 - *Cases*: 26 European countries
 - *Conditions*: Gross Domestic Product, employment protection legislation for regular workers, employment protection legislation for temporary workers, expenditures on active labor market policies (activation policies), and work-based learning in the curriculum (vocational education).
 - *Outcomes*: Having a high rate of young people not engaged in the labor force or in the education system because they are unemployed but are actively seeking work.
 - *Findings*: The authors found 3 sufficient combinations for having a high rate of unemployed NEETs. They were (1) having high employment protections combined with a strong economic downturn, (2) having “high employment protection for permanent and temporary worker and the lack of activation policies, and (3) High employment protection for regular worker and the lack of activation policies and vocational education” (pp. 107–108).
 - *Conclusions*: The authors suggest that findings from this analysis offer some hypotheses to evaluate in future research and also highlight the need for country-specific measures to reduce the rate of disengaged young persons.
- Van Kessel and colleagues used QCA to identify combinations of conditions related to inclusive education for persons with autism among European Union countries (van Kessel et al., 2021). The conditions evaluated stem from the Disability Rights in Education Model, which provided the conceptual framework for the analysis.
 - *Configural Question*: What EU member state policies are necessary or sufficient for having a high level of access for children with special education needs (SEN)?
 - *Cases*: 20 EU member states
 - *Conditions*: having a definition of special education needs, having a policy for the right to education for children with SEN, having supported teaching staff, having supportive services for children with SEN, having inclusive education policies, having a high level of parental involvement, having individualized learning outcomes, and having mixed mainstream classes
 - *Outcome*: Having access to education for children with SEN
 - *Findings*: Mixed classrooms, that is, classrooms that serve children with and without special needs, and support services for children with special needs were necessary components for inclusive education. Necessary components are those that are “must have” but alone may not be sufficient for achieving inclusive education. Five combinations of conditions were identified as sufficient for inclusive education; sufficient combinations are those that when present result in the outcome of inclusive education. The combination with the most empirical relevance was having policies focused on inclusive education combined with a high level of parental involvement and no established definition for special education needs.
 - *Conclusions*: The authors suggest that achieving inclusive education is a complex process with key policy areas that can be used in future studies as the development of inclusive education evolves.
- Dill and colleagues used QCA to explore combinations of organizational partnership characteristics and their relationship to frontline healthcare workers’ perceptions of career ladder quality and rewards after completing a workforce education and training program (Goicolea et al., 2015). The program relied on partnerships between healthcare organizations, educational institutions, and other workforce-improvement organizations to establish career ladders and professional growth opportunities for frontline workers. The study team conducted an analysis for each outcome (one is presented here).
 - *Configural Question*: What dimensions of healthcare organization and educational partnerships are necessary or sufficient for achieving frontline worker outcomes in career ladder programs?
 - *Cases*: 11 career development programs involving healthcare organization and educational organization partnership
 - *Conditions*: Management support/leadership in the employer and educational organization (i.e., having a manager leader, education leader, and frontline management support), having a long history with of partnership between the organizations, having a significant community need for the program, and having supportive organizational policies and practices in the employer and educational organization
 - *Outcomes*: Career self-efficacy, program satisfaction, work change/promotion, and college credit/credential provided
 - *Findings*: For career self-efficacy, the team identified the combination of having management support from an educational leader in combination with management support from a frontline manager and having supportive educational-institution policies as a sufficient combination, as well as having management support from an educational leader in combination with the organizational partnership having a long-standing history of collaboration and having supportive educational-institution policies.
 - *Conclusions*: This finding pointed to the importance of leadership support, as leaders could encourage frontline worker participation and engagement in the career ladder programs, while also having supportive policies and history of partnership, that supported successful implementation of the program.

- Bandaranayake used QCA to identify combinations of factors that might explain low versus high performance among secondary schools in Victoria, Australia (Bandaranayake, 2016). The factors evaluated included geographic location, a socio-educational index representing family backgrounds in terms of parent occupation and education, average student attitude and parental satisfaction, proportion of families with language other than English spoken at home, and average per student government funding.
 - *Configural Question*: “Why do different groups of government schools continue to perform well below the average and at inferior levels while another group of government schools performs consecutively and persistently well above the average and at superior levels? What are the conditions or causal complexities that govern polarization and continuation of educational inequalities?” (p. 589)
 - *Cases*: 49 secondary schools in Victoria, Australia
 - *Conditions*: High level of community advantage, high level of having language background other than English at home, student positive attitude toward school, parents have high satisfaction with school, and high level of state funding for school
 - *Outcomes*: High achievement of Victorian Certificate of Education (VCE) performance and low achievement of VCE performance
- *Findings*: The author identified 3 combinations of factors associated with high-performing schools; the combination with the highest empirical relevance included a high socioeducational index in combination with location in a metro area in combination with positive student attitudes (i.e., engagement and enjoyment of school). The author identified 5 combinations of factors associated with low-performing schools; the combination with the most empirical relevance included a low socio-educational index combined with low parental satisfaction.
- *Conclusions*: The author suggests that no single factor alone results in high or low performing school, and that the pathway to high performance is not simply the opposite of the pathway to low performance—a nice example of asymmetric causality. Further because some of the factors explored are immutable by schools themselves, inequalities across schools are likely to persist without attention to measures to prevent polarization and close gaps.

Process for using QCA

QCA involves an iterative process (see Fig. 1) and starts with having a configural research question. Ideally, this configural question is drawn from existing theory, scholarship, or conceptual frameworks, as theory and substantive knowledge inform the next steps of case, condition, and outcome selection. (Considerations for case, condition, and outcome selection are described below.) In this step, the researcher defines what cases are included and how the conditions and outcome will be specified in the analysis. After identifying the cases, conditions, and outcome, the researcher then calibrates the values for the conditions and outcome (calibration is discussed below). Analysis of the conditions and outcomes occurs next; analysis includes identifying individual and combinations of necessary and sufficient conditions for the outcome (i.e., identifying causal complexity) and conducting robustness tests. At this stage, the researcher may need to revisit earlier decisions about case selection or definitions of conditions and outcomes, or the researcher may proceed with exploring the solutions using a range of techniques, such as process tracing or case studies.

Considerations for use

In this section we describe some things researchers should consider when deciding whether QCA is an appropriate method for use in their research or evaluation. These include theoretical, empirical, and practical considerations.

First and foremost, QCA is designed to address configural research questions. QCA may be a good fit to address configural research questions that are part of a larger mixed methods study. QCA is not a method for statistical hypothesis testing. Further some research questions may be better suited for qualitative research designs. When implementing QCA in a mixed method design, researchers should consider where and how a QCA fits into the overall study design. In general, QCA serves as a complementary method to qualitative and quantitative strands of a mixed method study. If the QCA is meant to integrate qualitative and quantitative data strands, then planning for not only the data sources needed, but also the timing of the analysis will ensure that adequate analysis time is established in the project timeline.

In QCA, the case is the unit of analysis. As such, QCA is ideally suited for use with between 10 and 50 cases so that researchers have enough familiarity with each case to guide important analytic decisions (Rihoux and Ragin, 2009). However, the sample or population size alone should not drive the decision to use QCA. Although QCA is challenging to use with fewer than 10 cases, it can be used in large-N analyses, though consideration as to whether it is a good fit for the research questions is important. The cases included in a QCA should be similar enough to be comparable to each other; yet, they should not be exactly the same on all dimensions of interest. Moreover, case selection depends upon the researcher's theoretical framework and research question; a practical consideration informing case selection (as well as condition and outcome selection) is the feasibility of obtaining data (see below). Importantly, to evaluate which combinations of conditions are found among cases with an outcome, it is important to have cases with and without the outcome in the analysis (Schneider and Wagemann, 2012; Kahwati and Kane, 2020).

Fig. 1 Process for conducting a QCA Figure adapted from Kahwati LC, Kane HL. Qualitative comparative analysis in mixed methods research and evaluation. Vol 6: Sage Publications, 2020.

The availability and suitability of available data is a consideration. As with any method, if appropriate data sources are not available or have limited validity, then a QCA may not be feasible. When conducting a prospective study or evaluation, planning thoughtfully for a QCA at the outset of a data collection will facilitate use of the method, as researchers can ensure that relevant data are collected to support defining and assessing conditions and outcomes and that data sources are triangulated. However, because outcomes and potential variation is not known at the outset, one may find that all cases in the study achieved (or did not achieve) the outcome, which would limit use of QCA. When trying to implement a QCA after data collection has occurred, the researcher may face challenges in defining conditions and outcomes based solely on what information is readily available (Kahwati and Kane, 2020).

QCA uses calibration, rather than measurement, to assess conditions and outcomes (Schneider and Wagemann, 2012; Kahwati and Kane, 2020; Ragin, 2000, 2008). Calibration establishes the level of membership that a case has in a condition set or outcome set; it applies substantive and conceptual meaning to a measured value. Measurement of variables, in contrast, captures the degree to which a case has the property of the variable (Schneider and Wagemann, 2012). Ideally, calibration uses external standards to determine the level of membership (Schneider and Wagemann, 2010). For example, in the US secondary school system an "A" (excellent grade) is often determined by an average aggregated achievement level of 90% or more on evaluated work. The 90% or higher is a well-recognized standard for a high-level of achievement, and an individual scoring 90% or higher would have a high level of membership in the condition/outcome set of "high performance." A measured variable, for instance, would use the observed values of the achievement scores and apply measures of central tendency (i.e., mean, median, mode). Sometimes, however, external standards are not readily available. When that occurs, expert or substantive knowledge in the field can support decision making about level of membership in a set. Measures of central tendency (mean, median, mode) are not ideal for calibration because those are sample dependent (Schneider and Wagemann, 2010).

Use of software is essential when conducting a QCA. Several software programs are available; the two most commonly used are R's QCA and SetMethods modules and fsQCA (Ragin et al., 2008); each has benefits and limitations. Designed by Dusa (QCA

module (QCA)) and Oana and Schneider (SetMethods module (Oana and Schneider, 2018)), the R programs are updated regularly to stay abreast of ongoing enhancements to the method; however, R has a learning curve and can be frustrating to new users who are not familiar to working within the R environment. Designed by Ragin, fsQCA has a user-friendly interface, but has not been consistently updated and lacks some of the more advanced features contained in the R packages.

Like quantitative methods, a QCA may require model refinements and iterations, and, like qualitative, post-model analysis depends on delving into cases to make sense of the findings. Researchers, therefore, must plan use of time and financial resources to ensure that the QCA is implemented thoughtfully, that the model is thoroughly tested, and that the qualitative assessment of cases is comprehensive.

Because QCA is young and evolving as a method, many researchers and peer reviewers are unfamiliar with the method and may provide feedback on scholarly proposals or evaluations using QCA that are not relevant or appropriate. For example, more quantitatively-oriented researchers may comment on use of statistical controls for a model and question whether results are produced by chance; neither comment is relevant for QCA. Other reviewers may comment on QCA terminology (e.g., necessity, consistency) because they interpret the terms from the common usage perspective. Thus, when submitting a proposal or a manuscript for publication, one should strive to minimize use of jargon, offer explanatory analogies, use illustrative visuals (e.g., Venn diagrams), or create technical appendices and glossaries to aid reviewers' understanding.

Limitations

Although QCA offers a formalized and systematic approach to cross-case comparison, debate still exists in the research and evaluation communities about its use (Collier, 2014; Sartori, 2014). More quantitatively-oriented researchers question the robustness of QCA findings (Baumgartner and Thiem, 2015; Lucas and Szatrowski, 2014). However, QCA results are not meant to be statistically generalizable and can still describe patterns in data from the sample at hand. More qualitatively-oriented researchers question QCA's commitment to in-depth analysis of cases, which is the heart of the qualitative tradition (Thomann and Maggetti, 2017). Though some applications of QCA have not invested in the in-depth analysis of cases, "empirical intimacy" or deep knowledge of cases has been a part of the vision for QCA and is central to small- and intermediate-N applications of QCA (Rihoux and Ragin, 2009).

Concluding thoughts

QCA is still a relatively young method that is evolving. QCA experts continue to engage in ongoing dialogue with QCA's critics, making improvements to address limitations, and specifying new applications for QCA. Best practices associated with the use of QCA will continue to be refined in the upcoming years.

Glossary

Action research: “A participatory process concerned with developing practical knowing in the pursuit of worthwhile human purposes. It seeks to bring together action and reflection, theory and practice, in participation with others, in the pursuit of practical solutions to issues of pressing concern to people” (Reason and Bradbury, 2008, p. 4)

Adaptation: The degree to which an innovation is undergoing adjustments or modifications in the process of its adoption and implementation in real-life settings (Rogers, 1995).

Community-based participatory research: “A systematic inquiry, with the collaboration of those affected by the issue being studied, for purposes of education and taking action or effecting change” (Green and Mercer, 2001, p. 1927).

Dissemination and implementation research: Active approaches and planned research strategies to promote distribution and use of evidence-based interventions designed for specific audiences or populations (Rabin et al., 2008, National Institutes of Health, 2021).

Evidence-based practice: Objective, balanced, and responsible use of relevant research and best current data to guide scientifically based practice and policy decisions, to improve outcomes for consumers (Crime and Justice Institute at Community Resources for Justice, 2009).

Intersecting: Intentional combination of two or more methodological approaches within a study design (Plano Clark and Ivankova, 2016).

Knowledge translation: “A dynamic and iterative process that includes the synthesis, dissemination, exchange and ethically sound application of knowledge” in real-world settings (Straus et al., 2009, p. 165)

Translational research: Research aimed at moving knowledge and discovery obtained from the basic sciences to its application in clinical and community settings (Khoury et al., 2007).

Translational research continuum: Phases or stages in translational process corresponding to four knowledge translation concepts: translating knowledge from the basic sciences to humans (T1 research); translating the research findings to develop new treatments and programs (T2 research); translating evidence-based guidelines into everyday practice (T3 research); and translation to the community and real-world settings (T4 research) (Fort et al., 2017).

Translational science: The field of investigation which proposes to understand the scientific and operational principles which underscore each step and phase of the translational process (Collins, 2011).

Introduction

In recent years, there has been a tremendous growth in the use of mixed methods research across multiple disciplines (Coyle et al., 2016; Creswell and Plano Clark, 2018; Tashakkori et al., 2021). Mixed methods research is an approach where quantitative and qualitative methods are intentionally mixed during data collection, analysis, and interpretation within a study process (Creswell and Plano Clark, 2018). Thoughtful and intentional mixing of methods, data and results within one study allows researchers to examine the research landscape more widely from various lenses and viewpoints (Shorten and Smith, 2017). Moreover, a mixed methods approach allows investigators to explore complex issues and generate more complete and robust conclusions due to its notable methodological flexibility to intersect with other research approaches and designs (Creswell and Plano Clark, 2018; Nastasi and Hitchcock, 2016; Plano Clark and Ivankova, 2016).

Mixed methods can optimize the knowledge translation process and facilitate adoption of research findings into practice through adaptation, dissemination, implementation, and evaluation of complex interventions when intersected or meaningfully combined with translational research (Ivankova et al., 2018). Knowledge translation is defined as a multiphase and “dynamic process including the synthesis, dissemination, exchange, and ethically sound application of knowledge” into real-world settings through the use of translational research (Straus et al., 2009, p. 165). While there are different definitions of translational research, the most common definition is a type of research examining and gathering information aimed at moving knowledge and discovery obtained from the basic sciences to its application in clinical and community settings (Mace and Critchfield, 2010; Khoury et al., 2007). The focus of translational research is on translating and transforming knowledge. Knowledge synthesis is a critical component in the translational research process. Effective knowledge translation requires multiple methods and transdisciplinary approaches to generate results that are applicable in real time and settings (Khoury et al., 2010; Woods and Magyary, 2010). Using multiple methods and a team science approach helps researchers to incorporate best practices and produce solutions that have the greatest effect on people’s lives (Taylor et al., 2016).

The critical role of mixed methods in translating knowledge has been well-recognized (Creswell et al., 2018; Green et al., 2015; Ivankova et al., 2018; Meister, 2018; Palinkas and Cooper, 2017). Some noted advantages of using mixed methods within the field of translational research include: (1) integrating qualitative stakeholder engagement methods with quantitative outcome-oriented approaches; (2) examining the issue at individual and system levels and from multiple perspectives; and (3) providing an integrative thinking approach to addressing translation research questions (Martin, 2007). By intersecting mixed methods with translational research, educational researchers can increase the breadth and depth of understanding the pertinent issues related to knowledge translation and adoption of the evidenced-based practices in educational settings (Johnson et al., 2007).

This chapter offers a perspective on intersecting mixed methods with translational research. In the following sections we describe translational research and its integral components – evidence-based practice, adaptation, dissemination and implementation, and community-based participatory research and action research – and discuss how their intersection with mixed methods research provides a more methodologically robust approach to facilitate the knowledge translation process. We conclude the chapter with discussing advantages and challenges of using mixed methods in translational research and their implications for educational research and practice.

Translational research and translational science

Translational research emerged in the medical field stimulated by concerns over the extended time it takes to incorporate scientific discoveries in treatments, practices, and health policies (Wethington and Burgio, 2015). Translational research gained increased awareness after the National Institutes of Health (NIH) prioritized it in 2006 to bridge the gap between research and practice. Since then, it has been widely used across disciplines including education. A goal of translational research is to identify, support and promote sustainable adoption of evidenced-based practices. Using translational science, researchers integrate evidence-based practices, clinical experiences, and the individuals’ preferences to produce outcomes that impact population well-being (Taylor et al., 2016).

Translational research and translational science have been used interchangeably to describe the process of moving knowledge and discovery gained from the basic sciences to its application in professional and community settings. However, these terms differ in several ways (Austin, 2021). Zoellner and Porter (2017) describe translational research as a bidirectional process which purports to advance scientific discovery for patient and community benefit and involves multidisciplinary integration among basic, clinical, practice, population, and policy-based research. Translation is a practical multi-step process and is the focus of translational science. The latter is defined as the field of investigation which proposes to understand the scientific and operational principles which underscore each step and phase of the translational process (Collins, 2011). The intent of translational science is to advance the process of translation with results which can have a broader impact by utilizing effective research methods including mixed methods research.

Knowledge translation is a complex process consisting of multiple stages. The translational research continuum most commonly embraces four knowledge translation concepts: translating knowledge from the basic sciences (i.e. bench research including disciplines such as biochemistry, microbiology, or pharmacology) to humans, referred to as T1 research; translating research findings to develop new evidence-based treatments, programs and guidelines, referred to as T2 research; translating evidence-based guidelines into professional practice, referred to as T3 research; and translating evidence-based practices for adoption in the community and real-world settings, referred to as T4 research (Fort et al., 2017). While each stage builds upon and informs other stages, the

knowledge translation process is dynamic and iterative and includes synthesis, adaptation and dissemination of knowledge with continuous input from stakeholders (Callard et al., 2011; Straus et al., 2009).

Methodological components of the translational research process

Translational research is a multifaceted approach and incorporates different methodologies and approaches that contribute to the process of translating research findings into practice. The following five approaches, further referred to as the methodological components of the translational research process — evidence-based practice (EBP), adaptation, dissemination and implementation (D&I), community-based participatory research (CBPR), and action research — are integral to the knowledge translation process as each plays a specific role in facilitating translation of research findings to real-world applications (Ivankova et al., 2018). However, while pursuing different goals, they interact and inform each other in a joint effort to promote and facilitate the translation process.

In addition to having unique methodological characteristics, these five components employ mixed methods research by meaningfully integrating quantitative and qualitative methods to enhance and achieve knowledge translation goals. In the following sections, we describe these components and discuss how their intersection with mixed methods research enhances the knowledge translation process. We illustrate this intersection with examples of published studies that used mixed methods in translational research. We also draw on the perspectives of translational science researchers who apply mixed methods in their research practice and present these perspectives throughout the chapter. We collected those perspectives as part of the study aimed at understanding how mixed methods research can optimize translational science. **Box 1** provides a study overview including the study purpose, methods, and synopsis of the results.

Evidence-based practice

EBP is rooted in medicine with Archie Cochrane, a British epidemiologist, rebuking the medical community for their failure to critically examine evidence (Cochrane, 1972). Fundamental tenets of evidence-based medicine (EBM) include strategic awareness and critical appraisal of evidence to inform trustworthy and accurate decision making. EBP has been described as practice approach based on the best available evidence, patient/client preferences, and clinical judgment (Melnyk and Fineout-Overholt, 2019). In 2005, the Institute of Medicine (IOM) identified EBP as one of the core competencies for healthcare professionals. EBP is foundational to translational research and science.

EBP has been expanded from EBM to apply to other health and social science disciplines including education. The concept of evidence-based learning and teaching is complex and multifaceted. It is concerned with connecting learning and teaching to evidence-based methods, strategies and processes, through nurturing a systemic institutional culture invested in continuous improvement of student learning (Othie, 2018; Cranney and McDonald, 2012). A participant from the study we introduced in described the importance of EBP as the following:

Basically, the activities used to move innovations, bench science discoveries, policy innovations, you know, any sort of new significant event, ideally that is evidence-based into practice. Again, that kind of encompasses both bench science discoveries

Box 1 Study Overview

Title: Optimizing Translational Science: Role and Value of Mixed Methods Research.

Purpose: To understand how mixed methods research can optimize translational science by exploring the views and real-world experiences of translational researchers who apply mixed methods along the knowledge translation continuum.

Sample: Using purposeful and snowball sampling, we recruited 35 translational science researchers from two countries: US (n = 30) and Canada (n = 5).

Data Collection: Semi-structured interviews were conducted and recorded using Zoom web conferencing. The interview questions focused on participants' experiences with and views on applying mixed methods across the knowledge translation continuum from T1 to T4, and how mixed methods can optimize translational research through its different domains (evidence-based practice, adaptation, dissemination and implementation, community-based participatory research and action research). We also explored participants' perspectives on what researchers should be aware of when implementing integrated mixed methods studies in the translational research context. We also conducted follow up member checking interviews with 80% of the participants via Zoom and email.

Data Analysis: Interview transcripts were analyzed using inductive thematic and qualitative content analysis approaches with NVivo 12.6 Plus by several coders with regular input from the research team.

Results: Participants represented 10 disciplines including 8 participants from the education field. The majority (n = 31) served as faculty at academic institutions, three represented non-profit research organizations, and one was a program officer from the National Institutes of Health. Two-thirds were in senior ranks of full or associate professor (n = 22). Participants indicated that there are considerable advantages to using mixed methods in translational research; namely, the rigorous methodology of mixed methods, the potential to conduct practically focused outcomes research, and relevance of mixed methods across the translational spectrum. Participants also noted multiple challenges of incorporating mixed methods into the translational research spectrum. In particular, the time required to complete mixed methods research and the resources to ensure rigorous methodologies were often noted amongst participants as challenges of incorporating mixed methods into the translational research spectrum.

that eventually get translated into practical interventions; as well as, how ... we get those interventions to be adopted and utilized by practitioners and patients and so forth.

According to [Wisdom and Creswell \(2013\)](#), using a mixed methods approach can provide researchers with a deeper understanding of interactions, connections, or contradictions between qualitative and quantitative data. Incorporating the participants' voices, in which they share experiences of the process, can facilitate diverse means of exploration, enhancing the evidence, and providing opportunity for questions to be answered more thoroughly. This is essential to EBP. However, a robust process of using mixed methods can also add to the complexity of carrying out research that often requires more time, resources, and research training. Use of a multidisciplinary research team is critical to all aspects including sample selection, data analysis and synthesis or integration ([Wisdom and Creswell, 2013](#)). Our study participant explained:

... You need to have the personal experiences of people as well as the measurable quantitative outcomes. To really understand the real-world application, we need qualitative data, and we also need the quantitative data. And being able to put the two together using mixed methods designs ... would give us more insight than just using the quantitative results or the qualitative results.

[Aarons et al. \(2012\)](#) used mixed methods to examine the impact of EBP implementation and fidelity monitoring on staff retention in the context of an effectiveness trial of a statewide child welfare system change and EBP. Data used in the study were collected across a three-year period as part of a larger five-year longitudinal mixed methods project examining organizational factors influencing statewide implementation of an EBP throughout a network of private nonprofit community based mental health and social service provider organizations. The researchers described the unique aspect of their study as 2×2 experimental designs, in which the EBP versus services as usual (SAU) was crossed with the level of fidelity monitoring (monitored vs. non-monitored). There were 21 teams of home-based service providers operating in six regions covering an entire state, with approximately one-quarter of the teams operating in each study condition. For quantitative analyses, researchers examined both the independent effects of EBP and fidelity monitoring (framed as ongoing consultation for service providers) on provider turnover as well as the interaction of EBP and monitoring conditions on provider turnover.

Data were collected longitudinally using sequential and concurrent mixed methods designs. Quantitative data consisted of bi-annual web-based surveys of 153 home-based service providers and qualitative data included semi-structured interviews and focus groups with multiple stakeholders at three different intervals over a 3-year period. The results were interpreted looking for convergence and complementarity in both data sets and using expansion to explain unexpected results in one data set by the results from an alternative data set. Overall findings noted that EBP implementation has the potential to improve workforce outcomes as well as clinical outcomes. EBP implementation generally entails several costs including training, materials, fidelity monitoring and clinicians time away from clinical duties. Their findings suggested that policy makers and organization leaders consider these benefits, in addition to those of EBP utilization, in making decisions about EBP implementation.

Adaptation

Adaptation is defined as "the degree to which an innovation is undergoing adjustments or modifications in the process of its adoption and implementation in real-life settings" ([Rogers, 1995](#), p. 149). The concept of adaptation was advanced by [Rogers \(1995\)](#) as part of his Diffusion of Innovations Theory. This theory attempts to explain how a novel product, practice, or idea get adopted by different groups of people and focuses on assessing different aspects of the innovation, such as its complexity, relative advantage, compatibility with existing interventions, evidence of the positive effect and the readiness to adopt the innovation.

Since the innovation is not easily accepted by different people, adaptations of an innovation can fall under the following reasons ([McKleroy et al., 2006](#)), including the need to: (1) simplify a complex innovation; (2) address a lack of knowledge about the innovation; (3) focus in on a specific problem or expanding to other problems; (4) increase stakeholders' ownership of the innovation; (5) address the needs of more diverse population; (6) choose an appropriate form of innovation delivery; (7) respond to a change initiated by agency; and (8) fit the available resources. While modifications of the innovation during the adaptation process are necessary to increase the innovation uptake by different people, it is important to identify and preserve core components accounting for the quality and integrity of the intervention. Moreover, any adaptation process requires contextual knowledge of the target population's experience with the issue to be responsive to cultural practices and fit the worldviews of individuals involved ([Wingood and DiClemente, 2008](#); [Resnicow et al., 2000](#)).

Adaptation plays a crucial role in translating evidence-based research into practice, including education ([Chambers and Norton, 2016](#); [Brownson et al., 2012](#)). More specifically, adaptation can improve the fit of a certain intervention or educational program to a specific group of people by taking political, environmental, sociocultural, and economic factors into account ([Allen et al., 2012](#); [Chambers and Norton, 2016](#)). For example, groups in charge of the delivery of the innovation, characteristics of a specific population, unique characteristics of an organizational setting and resources are all factors that can immensely affect how the innovation gets adopted by a particular group in a particular community ([Cohen et al., 2008](#)).

Mixed methods research plays an integral role in the adaptation process because, for an adapted innovation to be successfully integrated and implemented, it must be viewed in multiple ways. One of our study participants observed, "A key issue for adaptation is understanding the context that you are trying to adapt to. I think mixed methods allows researchers to gather a better understanding of a particular context. I don't see how you can do an adequate job of that without conducting mixed methods research because you can't get those multiple viewpoints in any other way." Mixed methods research is particularly important when considering the culture and preferences of the population of interest. A study participant explained it in the following way: "Mixed methods can inform the content of the program, can inform cultural adaptations of both content and the delivery, can inform

adaptations that may be required to increase the feasibility of the program for the target population. It may also provide insight into evaluation outcomes that may be important to the stakeholders who you would like for them to continue to do the program. It can also give you ideas about how to improve your program."

Baydala et al. (2014) used mixed methods research to examine the cultural adaptation of the school-based drug and alcohol abuse prevention program for an Aboriginal community in Central Alberta, Canada. In their study, researchers worked with community members to utilize the Life Skills Training Program, which emphasized cultural perspectives, community values, and measurable short- and long-term outcomes. Several stakeholders such as community representatives, school personnel, and the Elders were included in the adaptation process. Stakeholders had weekly meetings to discuss the adaptation process, ensuring the process reflected the culture of the community and the school curriculum. Each stakeholder brought different perspectives in the meeting. For example, the Elders brought in traditional knowledge on appropriate language to utilize, cultural inclusion and practices; whereas, community members oversaw recording information and assisting the Elders commute back and forth from their residences.

The program was provided to elementary and junior high students at the Alexis Nakota Sioux Nation School and a mixed methods research approach was used to evaluate the impact of the program. A longitudinal survey of students was conducted to examine program fidelity and effect on the community. Seventeen students from grade 3 participated in the survey. Additionally, university researchers conducted several interviews throughout a 2-year span with various stakeholders to gather their perspectives on the effectiveness of the program. Lastly, data from the program implementation were collected and analyzed quantitatively to integrate with the qualitative interview findings. The integrated results demonstrated a positive effect of the program adaptation and implementation.

Dissemination and implementation

D&I research are active approaches and planned research strategies to promote distribution and use of evidence-based interventions designed for specific audiences or populations (Rabin et al., 2008; National Institutes of Health, 2021). Dissemination research can be defined as "an active approach of spreading evidence-based interventions to the target audience via determined channels using planned strategies" (Rabin et al., 2008, p. 118). Alternatively, implementation research is a "systematic inquiry regarding innovations enacted in controlled settings or in ordinary practice, the factors that influence innovation enactment, and the relationships between innovation, influential factors, and outcomes" (Century and Cassata, 2016, p. 170). As there is considerable overlap between the two concepts, many investigators and educators utilize the term 'D&I research' as an umbrella term for research focusing on both dissemination and implementation of an intervention (Rabin et al., 2008; National Institutes of Health, 2021).

D&I research is complex and requires an understanding of D&I research terminologies, theories, designs, analytic approaches, and practice-based considerations (Padek et al., 2015). Engaging multiple stakeholders, ensuring representation throughout the community, and building common goals are often required for successful D&I of an intervention (de Visser et al., 2020; Knoepke et al., 2019). Considering these complexities, specific and mentored training is often required to learn D&I approaches as these researchers use varying combinations of quantitative, qualitative, and mixed methods research to achieve intervention dissemination and implementation (Padek et al., 2018). As one of our participants noted, "When I started to work with translation and dissemination research, I realized that without qualitative methods, the quantitative data alone was not rich enough to understand processes." Notably, educators and training developers have created a list of educational competencies for D&I researchers and have outlined critical training components for mentored research in D&I to support these endeavors (Padek et al., 2015, 2018). Additionally, researchers developing a tool supporting systematic approaches for designing implementation research used multiple methods including qualitative methods, quantitative methods, and literature reviews to consolidate components of effective implementation research into a feasible tool and supplementary guide for conducting complex D&I research (Hull et al., 2019).

While the processes of D&I research are complex, the value of D&I approaches using rigorous research methods are highlighted in successful implementation and sustainability of education programs and interventions (Moir, 2018). For example, a study in Uganda found that a comprehensive extracurricular school-based AIDS education program was poorly implemented and had very little effect on improving students' knowledge about HIV and AIDS even after the program had been in place over a year (Kinsman et al., 2001). Employing a mixed methods evaluation, in which quantitative data were collected from 20 schools participating in the intervention and qualitative data were collected from focus groups among students within 5 of these schools, evaluators concluded that the program was not successful due to limitations in classroom time, fear of controversy, and inadequate training among teachers to implement the program. The use of mixed methods in this study was beneficial in illuminating barriers to successful implementation of the HIV education program; the investigators also noted that successful future implementation efforts were contingent on incorporating support for the educators and developing training programs to ensure the programs are implemented as intended.

In addition to identifying barriers to successful implementation of interventions or programs at a local level, mixed methods research can support implementation and evaluation of programs with wider dissemination efforts. As one of our participants noted about translational research, "It's really a global perspective, you have technology and you have society and want to have them work together, and you need to have ways of answering questions that address both the natural phenomena and the constraints we live in." For example, investigators developed, tested, and refined a harm reduction educational program to reduce HIV and hepatitis C transmission among people who inject drugs in France (Roux et al., 2021). The investigators disseminated the program to four other countries including Bulgaria, Greece, Portugal, and Romania to test the effectiveness of the program after adaptations were made for

different settings. Utilizing a multi-phased mixed methods implementation study design following the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) Qualitative Evaluation for Systematic Translation (QuEST) framework, the investigators were able to identify perceived benefits of the program, barriers to implementation, and the value of implementing educational interventions for people in Europe who inject drugs.

Community-based participatory research

CBPR is defined as a “systematic inquiry, with the collaboration of those affected by the issue being studied, for purposes of education and taking action or effecting change” (Green and Mercer, 2001, p. 1927). As a collaborative research approach, CBPR equitably involves all community members including recipients of interventions, practitioners, service agencies, community leaders, policy-makers, and other stakeholders in all phases of the research process (Isreal et al., 2001). CBPR is based on the idea that understanding the culture and epistemology of a community is key to the inquiry process (DeJonckheere et al., 2019; Lucero et al., 2018); thus, requiring partnerships between researchers and community representatives to design and implement studies reflecting community values and needs. Additionally, engagement of stakeholders in CBPR research designs enhances opportunities to address advocacy issues for marginalized groups and promotes inclusion of multiple voices (Ivankova and Wingo, 2022 (in press)). The CBPR process relies on nine core principles (Isreal et al., 1998, 2001), which were originally developed for public health but have been extensively applied by researchers across disciplines:

- recognizing community as a unit of identity;
- building on strengths and resources within the community;
- facilitating collaborative, equitable involvement of all partners in all phases of the research;
- integrating knowledge and action for mutual benefit of all partners;
- promoting a co-learning and empowering process that attends to social inequalities;
- involving a cyclical and iterative process;
- addressing health from both positive and ecological perspectives;
- disseminating findings and knowledge gained to all partners; and
- involving a long-term commitment by all partners.

Additionally, the likelihood that research findings grounded in evidence-based practices will be accepted and adopted by communities increases by fostering equitable partnerships, providing capacity building, promoting co-learning, and engaging community representatives from multiple settings in shared decision making. A study participant observed, “... CBPR is clearly an appropriate methodology for engaging communities to embrace and try to promote uptake for adoption of an intervention, because they’re the key stakeholders that are going to be able to say, why or why not this will work, and when. It’s why it will work, but how, here’s how it’s got to be delivered here.”

There are multiple advantages of intersecting mixed methods with CBPR in the context of translational research (DeJonckheere et al., 2019, Ivankova and Wingo, 2022 (in press)). Integrating quantitative and qualitative methods in a CBPR study design allows investigators to develop, implement, evaluate, and promote interventions that are effective and transferable to other communities and practices. A study participant explained: “... we look at theory and research to help us develop culturally informed, applicable research questions. And then how we develop these interventions that we can modify based on the cultural, community and contextual needs, and then implement those and then translate those into research and practice and policy.” By capitalizing on qualitative methods as part of mixed methods designs with CBPR, researchers can develop a better understanding of community culture and epistemology and enhance community members’ engagement with the intervention process and results.

Bogar et al. (2017) used mixed methods in a CBPR study to assess urban youth’s knowledge of and attitudes toward lead poisoning and other environmental health concerns. The researchers created a CBPR partnership with a doctoral candidate, an education coordinator, and youth advisory council consisting of eight young people ages 10–18 at a local youth organization. This partnership helped with a mixed methods study design, interpretation of the quantitative, qualitative, and mixed results and dissemination of the study findings. Engagement with young members of the community as co-researchers allowed investigators to identify and explore environmental health issues specific to the community, and to develop strategies for increasing environmental health literacy among urban youth attending after school community organization programming.

Data were collected through a survey of 105 youths and 12 focus groups with 64 young people. The survey aimed to assess knowledge and attitudes toward lead poisoning and focus groups further contextualized youth’s perceptions and understanding of the environmental concerns to inform tailored prevention education programs for young people. Integrated conclusions emphasized the importance of considering a local context and considering relevance of an educational intervention based on the social and economic factors in a community.

Action research

The concept of action research was originally introduced by Kurt Lewin to describe a research approach underscoring a practical focus, community-based orientation, change action, collaboration between participants and researchers, participant empowerment and importance of reflection (Lewin, 1948). As a systematic and cyclical approach that incorporates both quantitative and qualitative methods, action research aims to identify an action or intervention that will generate improvement and produce meaningful

change for those who have a vested interest in the issue (Hacker, 2013; Ivankova, 2015; Koshy et al., 2011; McNiff and Whitehead, 2011).

Action research consists of four iterative stages of reflecting, planning, acting, and observing and includes six methodological steps: identifying a problem, reconnaissance or fact finding, planning action, acting, evaluating action, and monitoring action (Lewin, 1948). Action or intervention is central to the idea of action research and requires a spiral of action cycles aimed at developing, implementing and evaluating action/intervention (Kemmis, 1982). Observing and reflecting on the effects of action/intervention and using this information for planning subsequent action cycles in collaboration with stakeholders provides an evidence-based approach to “jump-start” the process of translation and adoption of generated evidence into practice (Hacker, 2013, p. 103). A study participant observed, “From a translational research point of view you might be operating with a wonderful advantage because ... folks start to recognize the problem that they want to work on, that they wanna effect change, versus one where you’re going in and telling them that there’s a difficulty.” Engaging stakeholders in the process of change action through partnerships and active participation throughout the study process provides opportunities for creating more tailored and meaningful solutions that have better chances to be adopted in real-world settings. A study participant explained,

It’s going forward with a research question and making certain that all aspects are understood. And it can come from early input from stakeholders in terms of qualitative input, what their priorities are, what outcomes are important to them, all the way through sitting down and saying here’s what we found. Does it resonate with you? Do you see something else in the results that we can draw conclusions that would give us actionable items on?

A mixed methods approach has long been applied in action research due to its focus on finding comprehensive solutions to complex practical issues requiring the use of multiple sources of quantitative and qualitative evidence (Creswell, 2012; Ivankova, 2015; Koshy et al., 2011; Mills, 2011). The synergistic combination of mixed methods and action research allows investigators to address practical issues in a systematic and dialectic way by using multiple methods, drawing on multiple stakeholders’ perspectives, and producing more credible and valid results (Ivankova and Wingo, 2018).

Breimaier et al. (2015) used a participatory action research approach combined with mixed methods to identify effective strategies for the implementation of evidence-based guidelines for preventing falls among older patients by nurses in an Austrian teaching hospital. In Breimaier et al.’s (2015) study, a mixed methods approach was used to inform all phases in the action research cycle. In the diagnosing phase, researchers identified the problem that required exploration by using both mixed methods and action research to enhance understanding and buy-in of nurses to adopt and actively implement the tailored fall prevention guidelines for their patients. During the reconnaissance phase, quantitative survey and qualitative interview and focus group data were collected and analyzed to assess nurses’ knowledge and attitudes to the guidelines implementation and to explore potential facilitators and barriers both at the individual and organization levels. The quantitative and qualitative results were combined and compared to inform the selection of the implementation strategies tailored to nurses’ and patients’ needs and to develop the content of the educational intervention that would promote patient safety by reducing patient falls and their negative outcomes.

The intervention consisted of educational meetings with nurses, inclusion of local opinion leaders, compilation of informational folders, audit and adaptation of nursing record systems, and improvements in physical structure, facilities and equipment. The results of the educational intervention were evaluated twice using a concurrent mixed methods design at mid-term and at the project completion. The same quantitative survey instrument was used, and the same number of nurses were interviewed as in the reconnaissance phase to establish consistency in the evaluation of the intervention outcomes. The integrated evaluation results provided evidence about the effectiveness of the tailored implementation strategies, revealed potential facilitators and barriers both at the individual and organization levels, and outlined directions for further dissemination, implementation, and monitoring of the evidence-based generated practices. As a result of the study, nurses better understood the importance of creating a safer environment for patients and felt self-confident and empowered to explain the guidelines to their patients.

Conceptual model for intersecting mixed methods with translational research

As we have shown, the five methodological components of the translational research process play an important role in and provide a unique contribution to the process of translating research findings into practice. When meaningfully combined or intersected with mixed methods research, these components jointly expand the scope of knowledge translation and add rigor to the assessment of the translational research process and outcomes, thereby providing a way of integrative thinking for addressing complex problems.

Indeed, like Rothman’s causal pies in disease epidemiology (Rothman and Greenland, 2005), these translational research components are not mutually exclusive. Successful dissemination and implementation of research into practice depends on the nature of provided evidence, the contextual environment, and the mechanism by which the process is implemented in real-life settings (Kitson et al., 1998); whereas community and stakeholder engagement is critical for ensuring the evidence-based innovation is accepted and adopted. The process of innovation adaptation is integrated into the dissemination and implementation process, relying on stakeholders’ involvement and active participation in all stages using community-based participatory research methods (Allen et al., 2012). Action research, with its experiential learning and dynamic nature, focuses on the issues relevant to the community and provides a foundation for community-based participatory research (Faridi et al., 2007). The knowledge translation process is often iterative and involves cycles of observing, reflecting, planning, and acting to ensure that evidence-based generated findings are reflective of stakeholders’ views and experiences and are aimed at benefiting those affected by the issue (McNiff and Whitehead, 2011).

Ivankova et al. (2018) have advanced a conceptual model for intersecting mixed methods with translational research, which underscores the interaction of EBP, adaptation, D&I, CBPR, and action research with mixed methods research and with each other (Fig. 1). Mixed methods research takes a central position because it intersects with all five components by providing methodological support through a meaningful integration of the quantitative and qualitative approaches during the study design and implementation.

For example, Aarons et al. (2012) intersecting mixed methods with EBP to identify factors influencing staff turnover during a large-scale EBP intervention implementation in a state child welfare system. Using multiple types of quantitative and qualitative data in a sequential design, researchers were able to obtain convergent and complementary results to better understand the implementation context and the EBP fit in the organization; thereby enhancing knowledge translation. According to researchers, both quantitative and qualitative data were necessary to examine the EBP implementation process and its effects on staff turnover, while adding increased validity to the integrated study conclusions.

Baydala et al. (2014) used mixed methods research to evaluate the effectiveness of the culturally adapted school-based drug and alcohol abuse prevention program for Aboriginal youth. Using a CBPR approach, researchers engaged community members in the process of cultural program adaptation emphasizing community values, cultural perspectives, and measurable short- and long-term outcomes. To assess the program delivery and impact, qualitative data were collected over several years and included focus groups with school and community stakeholders and individual interviews with the elder members of the community. Quantitative data included pre- and post-assessment of students' health knowledge, attitudes, drug refusal skills, and self-esteem in the context of a sequential longitudinal cohort design. Intersecting mixed methods with a contextually responsive cultural adaptation approach allowed the researchers to conclude that culturally adapted EBP programs can have a positive effect on Aboriginal youngsters.

Kinsman et al. (2001) employed mixed methods research to conduct a large-scale evaluation of the implementation of a comprehensive extracurricular school-based AIDS education program in Uganda. Using a national sample of 20 schools and involving teachers in helping with data collection, researchers were able to obtain reliable information about the outcomes of the HIV educational intervention. The qualitative results from student interviews at the completion of the intervention provided corroborating evidence to the quantitative assessment of the intervention effectiveness and helped identify implementation barriers for further action. The mixed methods evaluation results indicated the need for more active teacher involvement with the program curriculum, potentially through CBPR and action research.

Bogar et al. (2017) intersected mixed methods with the CBPR approach by engaging young people with the mixed methods study design, study implementation and interpretation and dissemination of the results. Members of the Youth Advisory Council were instrumental in developing quantitative and qualitative data collection instruments, administering surveys, and facilitating focus groups capitalizing on their experiences and knowledge of the local community. As a result, young co-researchers were

Fig. 1 Intersecting mixed methods with translational research framework. Adapted from Ivankova et al. (2019) with permission of Dialectical Publishing.

able to identify environmental health issues unique to the young people in this community, which enhanced knowledge translation and prioritization among urban youth.

In Breimaier et al.'s (2015) study, mixed methods research informed all phases in the action research cycle. Both quantitative and qualitative data were collected and analyzed to assess nurses' knowledge and attitudes to fall-prevention guidelines implementation and to explore potential facilitators and barriers both at the individual and organization levels. The integrated results informed adaptation of the implementation strategies and the content of education sessions. Evaluation of the educational intervention also employed a mixed methods design and yielded rigorous insights about the implementation outcomes and directions for further dissemination, implementation, and monitoring of the evidence-based generated practices.

Advantages and challenges of intersecting mixed methods with translational research: implications for educational research and practice

There are multiple advantages of intersecting mixed methods with translational research. An obvious advantage is that mixed methods research can be used within all aspects of the knowledge translation process. All our study participants believed that mixed methods can be effectively applied in all stages of the knowledge translation continuum, from T1 to T4. At T1 stage, researchers should think about potential utility of their study results by considering stakeholder's perspectives and the quantitative indicators. At T2, evidence-based guidelines are formed by meaningfully combining evidence from multiple sources including quantitative and qualitative data. During T3 and T4 stages, employing mixed methods provides a holistic perspective by adding greater depth and scope to complex processes and allowing better understanding of intervention contexts and users by investigating their needs and values.

More specifically, mixed methods research enhances the knowledge translation process in the following ways. As a rigorous research methodology, mixed methods provides methodological support to EBP, adaptation, D&I, CBPR, and action research by enabling a more systematic approach to exploring, evaluating, disseminating, and implementing an innovation (Ivankova et al., 2018). A meaningful integration of multiple methods within a translational research project generates more valid inferences and informs the need and direction for innovation adaptation, dissemination, and implementation, thereby promoting transferability of evidence-based practices in real-world settings and creating a solid ground for sustainability of the innovation in a community of practice. As one of our participants observed about the role of mixed methods in bridging the gap between research and practice, "Mixed methods, if anything, helps connect researchers to the real world." This is particularly true in educational research aimed at correctly assessing students' knowledge and developing teaching and learning strategies that will be reflective of diverse students' needs.

A pragmatic nature of mixed methods research makes it advantageous in illuminating, assessing and supporting change over time without sacrificing the credibility and validity standards (Ivankova and Wingo, 2018; Perry, 2009). Using qualitative stakeholder-oriented methods, mixed methods research allows for creating contextual understandings of what may impact the process of knowledge translation by exploring stakeholders' perspectives, needs and experiences and integrating them with the quantitative outcomes data. Doing so, helps identify venues for engaging stakeholders and creating partnership to optimize adoption of research findings in practice similar to Kinsman et al.'s (2001) study that engaged teachers as co-researchers to evaluate the implementation of a comprehensive extracurricular school-based AIDS education program.

While there are considerable advantages, intersecting mixed methods with translational research is not a straightforward process and may involve several challenges for researchers. Conducting mixed methods translational research requires depth and breadth of expertise in quantitative, qualitative, mixed methods, and translational research methods; experience in data collection, management, and analysis of large volumes of data; facilities to conduct these types of research; and sufficient time to complete all phases of the study (Halcomb, 2019; Fudge et al., 2016; Wooten et al., 2014). As the need for individual expertise within each discipline is often noted in mixed methods research to maintain rigorous research methods and discipline specific standards, identifying collaborators with individual expertise and establishing discipline-specific team leaders may also be challenging in mixed methods translational research (Fudge et al., 2016; Roberge-Dao et al., 2019).

Beyond discipline-specific expertise, challenges persist in identifying investigators with personal characteristics that may support the intersection of mixed methods research with translational research continuum. In our study regarding the role and value of mixed methods to optimize translational research we also explored perspectives about the individual-level characteristics of mixed methods translational thinkers. We asked our participants to describe characteristics of researchers they considered to be mixed methods translational thinkers. Several characteristics emerged as common for mixed methods translational thinkers including: thinking in the context of the intervention to recognize the setting and potential value for stakeholders; an interest in the process of translation as well as the outcome; an interest in streamlining the timeframe from innovation development to adoption; and a willingness to explore alternative methods to support the translational research continuum. For example, one participant noted, "I'm learning every day, I am more and more open to creative study designs that are good for real world use." While additional research is needed to more fully explore the emerging concept of mixed methods translational thinking, individual characteristics that foster these perspectives may support the intersection of mixed methods and translational research.

Other challenges that have been noted by our study participants relate to the need for considering community priorities and engaging stakeholders with mixed methods translational research projects, requiring expertise in and understanding of mixed methods research. In educational settings, developing students' mixed methods skills and engaging them with translational research while carefully considering their interests and needs can help promote evidence-based practices aimed at educational improvements

and develop the sense of ownership for innovative learning and teaching practices. Time and resources to conduct mixed methods studies, due to its complexity and scope within a translational research continuum, are of critical importance and are particularly challenging when designing and implementing different components of the knowledge translation process.

Conclusion

Intersecting mixed methods with translational research and its integral components offers methodological advantages for translational research and practice and provides a methodologically robust foundation for optimizing the knowledge translation process. This intersection expands the scope of EBP, adaptation, D&I, CBPR, and action research and adds rigor to the assessment of the translational research process and outcomes; thereby providing a way of integrative thinking for addressing complex problems (Martin, 2007). The flexibility of mixed methods research to intersect with each of these components and its ability to facilitate different stages in the knowledge translation process, makes it advantageous for application in educational research and practice, creating and evaluating the learning environments that meet the needs of all students.

Introduction

Randomized Controlled Trials (RCTs) have become an increasingly popular approach in social science research. RCTs are commonly used to evaluate the effectiveness of interventions intended to change behavior and improve wellbeing. The core of the approach is that a set of individuals, households, schools, communities, firms, or any other unit of interest are randomly assigned to either receive the intervention (the treatment group) or to not do so (the control group, which may receive usual services, be put on a wait list, an alternative intervention or nothing at all).

The number of published RCTs has grown rapidly across social science disciplines: see, for example, trends in the rise of social work RCTs (Thyer, 2015), of education interventions (Connolly et al., 2018), and in the field of international development (White, 2019). Connolly et al. (2018) identified 1017 education RCTs, of which over three-quarters were in the period 2007–2016. And, notably, the Nobel Prize for Economics was awarded in 2019 for the use of RCTs to evaluate development interventions in low- and middle-income countries. Whilst RCTs have grown in popularity, they are also subject to a number of criticisms; see, for example, summaries of such criticisms in Connolly et al. (2018) and White (2013). Many of these criticisms may be overcome through the combination of RCTs with other methods as part of a mixed methods approach.

“Mixed methods” is often taken to mean the combination of quantitative and qualitative approaches. In this chapter, we use the term more broadly to mean the combination of any two different research or evaluation approaches; and in the context of RCTs, this means combining any non-RCT research or evaluation approach with an RCT. For example, a representative survey may be undertaken to assess the prevalence of an issue such as substance abuse amongst adolescents, combined with focus groups of adolescents to understand pathways into use. These are, respectively, quantitative and qualitative formative research which would inform intervention design.

In line with these definitions and with reference to common practice in health research, but less common in other social sciences, we recommend preceding an RCT (efficacy and effectiveness studies) of an education intervention with both formative research and formative evaluation, which may use both qualitative analysis and descriptive quantitative analysis. Without such initial steps, an RCT may be a waste of time and financial resources as we may not need an RCT to discover the reasons why the intervention does not work. Formative research may discover that the proposed intervention would be tackling the wrong problem or issue. Formative evaluation may find that the intervention as planned is infeasible for any one of a number of reasons.

Furthermore, if an intervention appears feasible following the formative evaluation, then an efficacy trial should be undertaken. Efficacy trials test whether the intervention has an effect when implemented with high fidelity to the intended target population. If the intervention is found to work in the efficacy study, then it should be taken to scale and subject to an effectiveness trial. Effectiveness trials test if the intervention has an effect when carried out under actual field conditions – so implementation fidelity is likely to be weaker and targeting to intended beneficiaries imperfect. Both the efficacy and effectiveness trials should have integrated mixed methods designs, which combine both impact evaluation (e.g. RCT) and process evaluation.

As such, mixed methods design is embedded in the approach following these four stages. Each stage is further elaborated in this chapter with examples particularly from education settings.

This chapter begins with a short discussion of terminology (Section **Terminology**), followed by a discussion of the advantages and disadvantages of using mixed methods with RCTs (Section **Advantages and disadvantages of mixed methods with RCT**). Section **Formative research and evaluation** describes formative research and evaluation, and Section **Efficacy and Effectiveness trials** describes the use of mixed methods in efficacy and effectiveness trials. Section **Conclusions** draws out our conclusions.

Terminology

Evaluation type and design

Terminology is not used consistently in the evaluation literature, so we begin by defining some terms.

First, we distinguish evaluation type and design. Regarding types of evaluation, Scriven proposed a dichotomy of formative and summative evaluation as the two types of evaluation. He defined these respectively as: “Formative evaluation is conducted during the development or improvement of a program or product” (1981, p. 63), and “Summative evaluation of a program (etc) is conducted after completion” (1981, p. 150). A second dichotomy of type distinguishes process evaluations and impact evaluations. As pointed out by Scriven (1996), this is different from the formative/summative dichotomy since both summative and formative evaluations may involve a process evaluation. Process evaluations assess the management and implementation of an intervention, and impact evaluations assess what difference the intervention has made to outcomes. In this definition, process evaluations rely on either quantitative or qualitative factual analysis, whereas the core of impact evaluation is a counterfactual analysis (that is comparing what happened with the intervention to the hypothetical case of the same group not receiving the intervention), though the latter is contested by some (see White, 2010).

Second, we refer to the evaluation design as all aspects of how the evaluation will be undertaken. That is (1) data collection, which covers both sampling (from whom data are collected) and data collection instruments and approaches (how data are collected), and (2) methods, which are how the data will be analyzed.

An RCT is a specific type of impact evaluation. A complete description of the design would include both sampling strategy, method of random assignment (e.g., cluster, simple, or matched pair, and how units are randomly assigned) and the way in which the data will be analyzed, e.g., t-tests of double difference of the means of outcomes, or instrumental variable regression with assignment as the instrument. A mixed methods RCT will include also a process evaluation, for which both sampling strategy and analysis will be different from the quantitative counterfactual analysis of effects.

Mixed methods research?

Mixed methods research is commonly taken to mean the combination of quantitative and qualitative approaches. There are two issues here. “Approaches” is a bit vague, and people often conflate type of data, or data collection, with methods (White, 2022). Neither focus groups or a sample survey are an analytical method. Our definition of design above clarifies this issue. So, a qualitative evaluation design should, for example, describe how focus group members are recruited, how the data from the group are recorded, and how they will be analyzed. For example, Gittelsohn et al.’s (2006) formative research to inform physical activity amongst girls in secondary schools states that the study covered six schools with purposive sampling for 80 individual interviews, and 11 focus groups with boys, and 13 groups with 100 girls in seventh and eighth grade. The focus groups covered a list of 44 open-ended questions, with the session lasting 45–60 min. A matrix-based analysis of themes from the focus groups was used, assisted by NUD*IST qualitative analysis software.

Second, we see the quant/qual distinction as too restricted. A further useful distinction, especially in the context of RCTs and other impact evaluations, is between factual and counterfactual analysis. Factual analysis, that is, simply what happened, can be used to address many questions of both research and policy interest. Factual analysis has no need of a control group. This can be illustrated with reference to three examples: the frequently neglected issues of targeting, understanding attrition and problem analysis.

First, take the example of targeting in after-school programmes. These programmes are generally universal. But one intent may be to reach children from disadvantaged backgrounds, for purposes of remedial education, for social and life skills development or as a diversionary activity from potential engagement with gangs or criminal behavior. Targeting can consist of both quantitative and qualitative factual data and analysis. Using quantitative data on participation we can calculate targeting errors: Type I error is the proportion of the target group who don’t participate, and Type II is the proportion of those attending who are not in the target group. A thematic analysis of qualitative data, collected from one-on-one interviews, focus groups or other less structured forms of data collection, can identify the reasons for targeting errors. Reasons for Type I error may include that there is a fee for attending, the fee may be waived but parents do not know that or are reluctant to apply for it (stigma, suspicion of authority, skepticism etc), or the child is enrolled but does not attend. It may also be the case that the school, or those running the aftercare, exclude children displaying disruptive behavior. Type II error can occur if the after-school program is a cost-effective means of childcare for working parents, so those who are better off may patronize it, and indeed influence content and activities to be less appealing to the target group.

The second example of factual analysis is understanding attrition in an RCT. Attrition is often unjustly neglected, with studies reporting what is called the “treatment of treated” which is the effect of those fully exposed to the intervention, which ignores those who dropped out or who didn’t show up in the first place. But, as argued by Gorard et al. (2017), the findings of many RCTs may be unsound as attrition reintroduces possible selection bias. The Institute of Education Sciences (IES) publishes acceptable thresholds for attrition, which show that even low levels of differential attrition between treatment and control undermine the validity of RCTs (IES, 2014). But, whilst many researchers may see attrition, as a technical inconvenience which may undermine the internal validity of their effect estimates, for the program implementer it is a failure which reduces the impact of their program, and so the program’s cost effectiveness and likely sustainability. Hence, researcher and implementer alike have a common interest in understanding and reducing attrition. Attrition is likely if the incentives for participation are not sufficient. This comes down to a simple cost-benefit

assessment on the part of the participant, including the assessment of the likelihood of detection and punishment if participation is mandatory.

Attrition is usually more complicated than simply participated or didn't participate. We can usually distinguish at least the following stages: get identified as a participant, referred or recruited, attend, maintain attendance, complete. The notion of the "funnel of attrition" captures the fact that children may drop out at any stage (see [White, 2014](#), on the funnel of attrition). Suppose 100 children are intended to participate in a program. Some of these notional 100 will not be identified as they may be street children, from currently homeless or nomadic families, be out of school or home-schooled, or being temporarily excluded. Suppose five per cent of potential participants are lost for these reasons. Not showing up is usually the reason for the largest drop in participation. This depends on the nature of the program, especially if it is mandatory or voluntary, in school hours on school premises or out of hours and elsewhere. For teenagers "turf" issues can affect their willingness to attend activities in off site venues. Another issue is parental consent which is increasingly required around the world: parents may not give it, or they may not get the letter home in the first place. Say 35% are lost at this stage, so the total number of children attending is 60, already less than two-thirds of the original target group.¹ But many of these 60 may drop out or only attend irregularly, so perhaps one-third are exposed to the full treatment. As in the case of targeting, the quantitative statement of attrition rates is best complemented by qualitative analysis to understand individual motivations which explain attrition.

Finally, is the often-neglected assessment of the intervention's problem analysis. Weak problem analysis, which is common in the absence of formative research, may lead to misdiagnosis and misleading explanations and understanding of project performance ([Dixon and Bamberger, 2022](#)). Using the same example of after-school programmes, with the targeted groups of students, additional factual analysis would help identify and verify if real problems have been targeted and appropriate solutions are provided by the proposed intervention. For example, if the real reason for not attending after-school programmes and related activities is due to that some parents are not even aware of them, then proposing measures such as increasing incentives (e.g., provision of vouchers) for participating may not directly help. The problem-based, tailored solution would be first exploring ways of conveying the messages to parents. Formative research is one way of addressing the gap in problem analysis by identifying priority issues, outcomes and key constraints to the success of any intervention. For example, by combining formative research (e.g., through interviews or focus groups with parents in this case) and a quantitative survey during the re-visit of the problem analysis would help figure out the diagnostic issue so that timely adjustment could be made.

Advantages and disadvantages of mixed methods with RCT

Evaluation should be issues-led not methods-led. Different evaluation types and designs are most appropriate depending on the evaluation purpose and questions. The choice of appropriate evaluation design depends on several factors such as the nature of the intervention, evaluation purpose and scope, context, and a range of operational and policy issues (; [Stern et al., 2012](#); [White, 2010](#)). Mixed methods designs can be usefully added to RCTs, as RCTs are the most appropriate design for addressing the question of causal effects, but that is not the only question of interest to both researchers and practitioners.

Mixed methods bring in a range of benefits. In addition to enabling triangulation by providing complementary data and findings drawn from these data, mixed methods design allows analysis of each individual program component instead of using one unified design ("black box") for largely different components ([White, 2014](#); [Yang, 2018](#)). And most importantly, mixed methods deepen the explanatory power of a study – unpacking the causal mechanisms² of a program to understand how and why the program works and the intermediary outcomes connecting inputs, outputs and outcomes to achieve the desired impact or goal [Creswell et al. \(2009\)](#), [Drabble et al. \(2014\)](#), [Edmunds et al. \(2021\)](#), [Plano Clark et al. \(2013\)](#), [Song et al. \(2010\)](#), [White \(2008, 2013\)](#), and [Yang \(2018\)](#).

For example, in education research and evaluation, the use of RCTs has drawn critiques regarding its feasibility in the education sector, its neglect of context and experiences and the tendency to make over-simplistic universal causal claims ([Connolly et al., 2018](#)). These criticisms can be largely countered with a mixed methods approach – embedding RCTs in a broader evaluation design, which combines the counterfactual analysis of attribution with a factual analysis across the causal chain, or adding process evaluation to RCTs under an overarching theory-based evaluation design. However, mixed methods design requires the right technical expertise and will add to the total evaluation budget.

There are various ways of mixing or combining methods. [Carvalho and White \(1997\)](#) proposed three ways of employing mixed methods in below [Table 1](#): that is (1) integrating, where the qualitative work informs the design or interpretation of the quantitative component or vice versa; (2) confirming, refuting, enriching, or explaining where qualitative findings help validate and add color to a quantitative finding, or conflict with it which then needs further exploration (for example, we suggested above that qualitative methods are best suited for understanding targeting success and failure, and attrition); and (3) merging the findings to draw out a single set of implications for policy, practice and research. The choice of specific way of mixing and matching, combining or

¹The funnel of attrition continues to operate on outcomes along the causal chain to learning outcomes. Children need to show up to class, pay attention, understand the material, and apply it to internalize ("learn") it. Only a small percentage make it to the last stage.

²A program mechanism focus needs to unpack what particular aspects or components of a program make it work, or indicates how both macro and micro processes construct and influence the program ([Pawson and Tilley, 1997](#), p. 66).

Table 1 Different ways to combine quantitative and qualitative methods.

<i>Typology of mixing methods</i>	<i>Specific ways to operationalize the use of mixed methods</i>
(1) Integrating methodologies	• Using quantitative baseline survey data to determine the individuals/communities to be studied through the qualitative approach • Using the quantitative baseline survey to inform the design the interview guide of the qualitative survey by identifying issues of interest • Using qualitative work to determine beneficiary selection for the intervention and possible stratification of the RCT (quantitative) sample • Using qualitative work to inform the design of the quantitative survey questionnaire, e.g. outcome selection and definition • Using qualitative work to pre-test the quantitative survey questionnaire • And/or using qualitative analyses to refine, for example, measurement tools e.g. an index of deprivation
(2) Confirming, refuting, enriching, and explaining the findings of one approach with those of the other	• “Confirming” or “refuting” are achieved by verifying quantitative results through the qualitative approach. • “Enriching” is achieved by using qualitative work to identify issues or obtain information on variables not obtained by quantitative surveys. • “Examining” refers to generating hypothesis from qualitative work for testing through the quantitative approach. • “Explaining” involves using qualitative work to understand results from quantitative data, in particular the lower parts of the causal chain.
(3) Merging the findings of the two approaches into one set of policy recommendations	Analyzing the information provided both by the quantitative approach as well as the qualitative approach to derive one set of implications for policy, practice or research.

Source: Adapted from [Carvalho and White \(1997, p. v\)](#).

integrating methods is determined by specific context, research and evaluation questions, purposes and scope. Examples of these uses are given in [Table 1](#).

This typology also applies to the use of mixed methods with RCTs in various ways. Different types of quantitative and qualitative methods or factual and counterfactual analysis, can be combined as shown as ways of operationalizing in the right column of [Table 1](#) to achieve the ends (e.g., aim or purpose of mixing methods) as shown in the left column of [Table 1](#).

Formative research and evaluation

Formative research and evaluation are two initial stages which are often unduly neglected. Formative research is undertaken to help shape an intervention which is planned but not yet fully, or at all, designed. Formative evaluation is an initial field testing of the feasibility of the intervention in the intended setting. As emphasized above, terminology is not standard, so what we would call formative evaluation is sometimes called formative research, and what we would call summative process evaluation is sometimes labeled as formative evaluation.³

Formative research

Formative research thus takes place before any intervention starts as the role of the research is to inform intervention design. It is by its nature, factual not counterfactual, and may use both quantitative and qualitative data. Formative research may be used to identify both priority issues or outcomes, and the most important constraints to improving those outcomes which should be addressed

³We found examples of each of these in our search for case to use in this chapter.

by any intervention if it is to succeed. Using formative research prior to undertaking an RCT is, by definition, mixing methods across the whole research design, even if the formative research is purely qualitative and the RCT purely quantitative.

Sherry (2013) compares the substantial formative research behind the successful educational television program *Sesame Street* with the lack of such research, and subsequent millions of dollars wasted, in developing educational video games. For example, comedy writers were hired to write the *Sesame Street* scripts as it was found that writers could be taught to teach, but teachers could not be taught to write suitable scripts. *Sesame Street* has subsequently been found to improve children's learning outcomes in a number of countries around the world (e.g., Ball and Bogatz, 1970, on the first season in the United States, and Diaz-Guerrero et al., 1976, on Mexico, and Fluent Public Opinion and Market Research, 2008, on Kosovo).

Another example comes from the US National Heart, Lung, and Blood Institute's Trial of Activity for Adolescent Girls (TAAG), a multi-center, multicomponent, randomized field trial of 36 middle schools, of a multicomponent intervention linking schools with community organizations to reduce the age-related decline in physical activity in middle school girls. The design of TAAG involved extensive formative research with a range of methods including survey (e.g., with schools, parents and community agency), in-depth interviews, focus groups and activity checklist (Gittelsohn et al., 2006). For example, focus groups were conducted at the six TAAG field sites during the formative research to help identify audience segments, which were labeled athletic, preppy, quiet, rebel, smart, tough, and other. When responding to the question about barriers to participating in physical activity, for instance, focus groups felt preppy girls were concerned about appearance, injury and time, which helped generate messages in relation to themes featuring fashionable girls and social opportunities. In contrast, quiet girls were more concerned about embarrassment, shyness, uncertainty about what they may be supposed to do or believe that they don't fit in. The appropriate messages for this group stress comfort and ability to be active either alone or with small groups of friends (Staten et al., 2006).

Formative research can address the following questions

- What are the priority outcomes? These priorities can be determined through an examination of current strategy, engagement with decision-makers and implementing agency, and consultation with the intended beneficiaries. Other than the beneficiary consultation (which might use a sample survey), these exercises typically have small samples, so that quantitative approaches are not appropriate. Qualitative thematic analysis will be most appropriate. Different stakeholders may well have different priorities, so some transparency is required in the decision-making. This transparency is also good research practice as qualitative studies are often poor at describing their methodology. Who was consulted, why these people and how were they selected? How was the analysis undertaken in a way to ensure that the reported findings are an accurate representation?
- Given the desired outcome, what are the binding constraints on achieving that outcome? Interventions will not achieve their intended goal if the binding constraints remain untackled. If the goal is to improve learning outcomes for disadvantaged children, are the worst performing children not attending school or being excluded, so that issue need to be addressed? Is teacher absenteeism or lack of learning materials a problem? Related formative research questions are about barriers to children attending school and barriers to effective learning.
- For example, the policy issue of concern may be increasing access to tertiary education to students from disadvantaged backgrounds. Obvious policy solutions may seem to be positive discrimination or quotas in university places, targeted grants for fees and living expenses, scholarship programmes or providing information about the benefits of tertiary education to children and their parents. But formative research could show that the issue is ensuring that children from disadvantaged backgrounds complete secondary education. Hence, although the policy goal is to increase participation of children from disadvantaged backgrounds in tertiary education, the appropriate interventions may be at secondary, not tertiary, level. Indeed, taking the long view, the most cost-effective intervention may be early childhood development (ECD) programmes such as parenting classes to encourage parents to provide the stimulation to a child to support cognitive development.
- Another important question is to assess the existing provision for what a project plans to do. For a computer-assisted learning project, what technology do children already have access to? If considering ECD interventions, what are existing childcare provision and practice?
- What is the feasibility of undertaking the intervention in the planned context? This may involve discussions with teachers and teacher unions, NGOs/charities, parents and children themselves, as well as an examination of context and existing interventions.
- Establishing the target group: who are the groups that would benefit most from the intervention and are receptive to it?
- Formative research may establish priority issues. What do communities care about? Is it clean water, jobs, quality of schooling or something else? These issues could be addressed through key informant interviews with community leaders, townhall-style community meetings or quantitative opinion surveys. If using quantitative surveys some initial qualitative work is advised to ensure that the full range of relevant options are included in the questionnaire.

Formative evaluation

Interventions commonly fail for one of three reasons: low acceptability in the target population, technical failures, and poor implementation. The first two of these can be anticipated by a good formative evaluation, which will usually be qualitative in nature. Formative evaluation is simply trying the program out on a very small scale. This is not efficacy testing – that comes next. This stage is simply to see if the intervention makes sense. Large scale evaluations costing large amounts of money often identify reasons for

failure which could have been anticipated by a good formative evaluation, such as textbooks at too advanced a level, providing computers to schools without electricity or advising teachers to arrange their desks in circles not rows when the schools have no desks. As with formative research, undertaking formative evaluation prior to the RCT is a mixed methods approach, even if the formative evaluation is purely qualitative.

Low acceptability may come for many reasons. Parents do not send their children to after-school activities as they are needed to collect water, do domestic chores and look after younger siblings. Girls refuse to attend special sessions for those designated as being at high risk of teenage pregnancy because of the stigma - the lesson of labeling theory is that you should avoid labeling, whereas such programmes may do the opposite. Children may resist after-school activities which are simply seen as "more school".

Technical issues are most obvious with technology: providing computers in schools without also providing appropriate software has been a notable cause of failure. Of course, providing computers to schools without electricity is a more obvious, though thankfully less common one. But it can apply to all teaching equipment and materials, such as telling teachers to put the children's desks in circles and posters on the walls when they have neither desks nor posters - nor, even, walls (White and Masset, 2003). Textbooks can be at the wrong level (too high or too low) or simply in the wrong language.

An example of formative evaluation comes from an educational assessment technology innovation Assessment Tools for Teaching and Learning (asTTle) educational software, in New Zealand (Hattie et al., 2006).⁴ The study aimed to gather insights, feedback and related effects with the deployment of the innovative education technology, particularly from the end-users' perspective (e.g., teachers, students, and school leaders), and to learn about areas for future improvement. Study components included teacher and student evaluation of the test materials, the accuracy and added value of the reports, the reactions and effects of the professional development, and the evaluation of the utility of the software. Multiple methods were combined during the evaluation including questionnaire surveys designed for teachers to seek their feedback on the asTTle test questions, tasks, and instructions; student surveys to gather their views about the test materials at the end of a trial test; focus groups and additional survey questionnaires to examine the accuracy of understanding of teachers in relation to asTTle reports; telephone interviews, questionnaire surveys, and field visits undertaken to look at the effectiveness of the software and its professional development resources and processes. For example, in terms of the understanding of asTTle reports, evaluations in primary schools found that teachers who best understood the asTTle results made more positive and fewer negative comments. Those who made the most negative comments appeared to be due to their poor understanding of the reports. This finding led the program to include additional assistance needed by teachers for correctly understanding and using asTTle. The use of mixed methods (both quantitative and qualitative) in this case showcases the typology in Table 1 that information obtained from different tools helps enrich one another and their findings can get merged to generate learnings and (program) policy implications.

A further example is a study commissioned by the William and Flora Hewlett Foundation who engaged edBridge Partners to conduct a formative evaluation of open education networks in North America in both K-12 and higher education, and their role and efforts in developing an inclusive and responsive open education field (edBridge, 2021). The evaluation sought to examine how well the open education networks are engaging various stakeholders, other actors and communities and serving their needs, and so to provide network leaders and organizers with evidence to inform how they can adjust and sustain their networks and the open education field. A range of mainly qualitative methods were used to gather the perceptions and beliefs of open education network leaders. Approaches used included landscape analysis (e.g., involving higher education and K-12 sector open education fields to identify networks and key actors and to examine the intersection between networks and sectors); surveys (e.g., with various groups of network leaders such as those of regional networks: states, provinces, and school districts), in-depth interviews with key leaders, and a series of facilitated dialogues (edBridge, 2021). For example, in terms of the effectiveness in engaging and serving the stakeholders, when responding to the question "how would you rate your network in its ability to serve its audience or stakeholders?" 77% of respondents rated their networks as Good or Excellent. Factors underlying positive responses were strong relationships, established systems and mechanisms which were found helpful for leaders to expand reach and best serve stakeholders. Perceptions about limitations were more about limited resources or the need for more intentional and focused efforts in networks. Accordingly, relevant recommendations were raised for future endeavor such as expanding outreach to funders and seeking collaborative opportunities (Ibid). This example adopts mixed methods in the way that findings from both quantitative and qualitative studies are merged to gather evidence-based recommendations, as illustrated in Table 1.

The Center for Evidence and Implementation (CEI) conducted a formative evaluation of a EduCarer Aide Training (ECAT) project by Presbyterian Community Services (PCS)⁵ in Singapore (CEI, 2022). The ECAT project is a capability-building initiative focusing on special education school graduates - helping build their skills for employment in pre-school settings and increasing their confidence and self-esteem through providing center-based modular training and on-site (e.g., classroom) coaching in pre-schools. The formative evaluation sought to review existing implementation mechanisms and examine preliminary effectiveness of the project to gather learning and improvement and to determine the possibility of scale-up. CEI revisited the project logic with the program team, reviewed and advised on the improvement of the curriculum and also conducted semi-structured interviews with the trainees to gather insights and information on the project performance. The formative evaluation revealed that the project

⁴A software that automates assessment capacity not by delivering interactive on-screen test questions, tasks, or portfolios as suggested by several educational technologists, but by integrating computer-aided test assembly with computer analysis of test performance into a teacher-controlled, curriculum-based system that graphically reports student achievement against norms, objectives, and standards. asTTle is a combination of computer-based and computer-assisted assessment with networking capability (Hattie et al., 2006, pp. 4-5).

⁵A social service agency registered with the National Council of Social Service in Singapore.

had good early potential to be scaled up to the national level and that there were possibilities in terms of building skills of people with disabilities for better employment opportunities and quality of life (CEI, 2022). This case applies a range of methods with a qualitative focus, findings gathered from each tool help enrich and triangulate one another.

Efficacy and effectiveness trials

Efficacy is testing if a program works when done in the target population and high implementation fidelity. Factual monitoring data makes sure things going according to plan. Qualitative process evaluation data identify implementation issues. An efficacy trial also of course measures the effect of the intervention. The non-RCT component of an efficacy may repeat some of the formative evaluation questions, but also uses process evaluation to better understand the causal chain.

Effectiveness tests the program at scale as it will be implemented in “real life”. For example, in efficacy trials the research team may be involved in implementation but that won’t be true at effectiveness. Hence at effectiveness stage, implementation issues still need to be evaluated. It is often the case that successful programmes at the pilot stage fail when taken to scale, the cause being poor implementation fidelity. A well know example is a study of contract teaching in Kenya, which found that the intervention improved student test scores when implemented at scale by NGOs but not when implemented by government agencies (Bold et al., 2013).

The Education Endowment Foundation (EEF) in the UK engaged the Sheffield Institute of Education to review its scale-up of EEF efficacy trials to effectiveness trials (the efficacy–effectiveness continuum) completed by 2019 (some of the trials adopted RCTs) to provide insights and support for the EEF, developers and delivery partners in the design and management of the scale-up of trials. The study involved a quantitative comparison of the effects at the efficacy and effectiveness stages and analyses of qualitative interviews with program team members and leaders to identify influencing factors – models, structures, processes and program features that either support or hinder intervention scale-up. A process evaluation was embedded here following the efficacy and effectiveness trials. For instance, the quantitative study found the mean unweighted effect size for seven interventions fell from 0.25 for the efficacy trials to 0.01 for the effectiveness trials. This change may result from the differences between the two trials in their design, target group, size of study and the geographical coverage (e.g., effectiveness trials were larger studies based in primary schools). The qualitative analysis found that facilitators for successful implementation at scale were clearly established structures and processes (including quality assurance of training and implementation), access to in-depth expertise on the intervention and its implementation, highly skilled trainers with experiences in children learning, teaching relevant subjects and working in school settings. These findings implied that a more systematic and evidence-based approach may be needed to bring in more clarity on necessary changes or inputs for intervention scale-up (Maxwell et al., 2021). Linking back to Table 1, this case exemplifies the way that mixed methods (e.g., RCTs and non-RCT methods) get applied and their findings merged to generate one set of policy implications.

The Learning Together intervention on bullying and aggression in English secondary schools (Bonell et al., 2018) serves a good example in terms of using mixed methods in RCTs in an educational setting – it combines and embeds economic and process evaluations to examine different key aspects and fulfill different information needs. The intervention aimed to modify the school environment through reducing bullying and aggression and improving student health and wellbeing across various domains. Following a pilot trial in eight schools to demonstrate feasibility and acceptability among participants, this inclusive cluster randomized trial was undertaken in 40 schools in England together with process and economic evaluations. The process evaluation intended to assess factors in relation to implementation, context, acceptability and employed qualitative methods such as case studies (six intervention schools were selected for in-depth assessment) and focus groups with students and staff. The economic evaluation applied a cost-consequence analysis including all main outcomes and evaluated incremental effects at 24 months and 36 months since randomization, with costs relating to use of education, police, NHS resources (e.g., through student survey questionnaires) and staff time (through staff survey questionnaire), and payment for facilitators and trainers. This application of mixed methods in education RCTs helps provide a more complete picture and evidence chain and add explanatory power especially in the complex educational context. Results showed positive effects despite the variable fidelity to this whole-school intervention – it had small but significant effects on bullying but no effect on aggression. This intervention and its findings had important implications for public health policy – a single and very low-cost intervention could bring a set of important public health-related outcomes – and for the evidence base on the feasibility and effectiveness of using whole-school approach to preventing bullying and aggression and promoting student health in broader high-income, middle-income, and low-income settings. The use of mixed methods in education RCTs in this case corresponds to the typology in Table 1 – enriching or supplementing data sets with different methods and merging results to provide evidence-based implications for policy and research.

The Continuing Professional Development (CPD) programmes in the UK were initiated to support teachers responsible for teaching science in primary schools with subject-specific knowledge and pedagogical content knowledge, as well as leadership training (e.g., leading the science provision in schools). An evaluative study (Bennett et al., 2019) was undertaken to generate evidence on the program impacts and to inform the decision-making of the possible national roll-out. The evaluation used mixed methods approach by integrating a RCT (conducted with three groups including a full treatment group receiving the full CPD program, a partial treatment group with the short CPD program, and a control group) with a series of case studies with a subset of approximately one-third of the schools in each of the three RCT groups. Under the case studies, the evaluation team conducted site visits to interview key respondents such as science specialists, teaching colleagues and management staff to gather their respective beliefs, perceptions and perspectives on the program, and to observe some of the teaching practices in classrooms. This mixed methods RCT approach helped triangulate and validate results from different data sources and provide a more complete picture of

the reality. For example, findings from the quantitative data from the RCT through the assessment of teachers' subject knowledge did not show statistically significant impact on teachers' performance after receiving the full or the partial training programmes; whereas the qualitative evidence indicated many teachers participating in the full intervention perceived improved subject knowledge and increased confidence in teaching science. This was corroborated by evidence found during lesson observations – changes in teachers' practice and etc. This example of mixed methods RCT showcases the way how data from different methods are “confirming” or “refuting” one another as indicated in [Table 1](#). Specifically, results from qualitative studies refute to some extent those from the quantitative process in this case.

The eSchool 360 model implemented by Impact Network in Zambia delivers low-cost education to children in rural communities through a holistic solution with the aim of improving educational outcomes by incorporating three key components: a standardized e-learning curriculum and pedagogy, ongoing teacher training and professional development, and community ownership. The American Institutes for Research has been engaged in the evaluation of this model by designing and implementing a mixed methods cluster-randomized controlled trial (cluster-RCT) – an impact evaluation through the cluster-RCT (63 eligible schools have been randomly assigned to either the treatment or control group), a cost-effectiveness analysis (assessment of the costs of the model using the ingredients method which needs to specify all ingredients necessary to replicate the model and then collect data on the unit costs of these ingredients), and a process evaluation (assessing the fidelity of implementation). Specifically, the qualitative process evaluation complements the impact evaluation using RCT and explores informal patterns, unanticipated interactions and unforeseen areas of interest in addition to formal activities and anticipated results; it also helps pursue in-depth understanding of why or why not the program shows impact (e.g., facilitators and barriers) as well as contextual factors. Qualitative methods such as key informant interviews, focus group discussions and classroom observations are employed to collect relevant data ([Hoop et al., 2020](#)). The results of this mixed methods cluster-RCT showed statistically significant intention-to-treat effects in the primary cognitive skills outcomes such as the early grade reading assessment, early grade mathematics assessment, the Zambian Achievement Test, and Oral Vocabulary assessment scores. The findings from the qualitative evaluation process verified those from quantitative studies – respondents perceived highly of the quality of education and improvements in literacy at IN schools (though less reported improvements in numeracy). It was also revealed that the high level of implementation fidelity should have contributed to the positive effects found in learning outcomes, and that there remains considerable room for further improvements and evaluation of longer-term effectiveness of the intervention. This case serves an example of using findings from the qualitative evaluation process to verify and confirm those from quantitative studies.

All of these examples show how qualitative methods can help strengthen external validity. A single RCT cannot be the basis for a universal causal claim. But a good understanding of contextual factors which condition success or failure of an intervention can help us understand the settings to which findings may be transferred, and so when, where and how we may try a transfer an intervention which has been tested elsewhere. The principle of transferability of evidence findings underpins the evidence revolution and the work of What Works Centers, such as the Education Endowment Foundation ([White, 2019](#)), so further research to strengthen our confidence in transferability is an important area of work.

Conclusions

RCTs are criticized for a black box approach, unable to disentangle causal pathways. The black box may in fact be a blessing not a curse ([White, 2014](#)). It is incorrectly argued that the black box means RCTs cannot evaluate complex interventions with multiple, interacting causal pathways. Their strength is that they can make valid statements about causality in precisely these circumstances. However, in general it is better to go beyond “bare bones RCTs” to answer a broader range of questions of interest to policy makers and practitioners.

However, in this chapter we have also argued a different point to the usual emphasis on combining qualitative approaches into a quantitative RCT. We argue that when planning an RCT prior stages of non-RCT research are necessary – and that such an approach is by definition a mixed methods approach. Formative research helps identify priority outcomes and the issues to be addressed by any intervention intended to support the achievement of those outcomes. Formative evaluation assesses the feasibility of the proposed intervention, most usually through qualitative fieldwork. This approach is common in health research, and our paper illustrates examples of its use in the education field.

Hence, we propose not just incorporating non-RCT methods into RCTs evaluation designs, but undertaking non-RCT studies, that is formative research and evaluation, before moving onto RCT-based efficacy and effectiveness trials. Funders should make such an analysis a pre-condition for support for an RCT.

And, we also make the case, as is now quite commonly argued, that the RCT itself should combine both quantitative and qualitative methods. As is widely accepted, evaluations should be issues-driven not methods-driven. Hence a range of methods – quantitative and qualitative, factual and counterfactual – should be used in evaluations. RCTs are the most appropriate approach for answering questions about effectiveness. Complementing RCTs with process evaluation will shed light on implementation issues, as well as understand contextual factors to help understand the extent to which findings are transferable. Too many RCTs provide too little information on the intervention and context, which make them less useful than they would otherwise be. Using mixed methods brings more of this detail to the study.

There are various ways of using mixing methods as exemplified in [Table 1](#), which show an iteration between quantitative and qualitative. Leading intervention and RCT design by formative research and evaluation is an example of qualitative research

informing quantitative research. But the baseline survey for the RCT may also identify issues warranting further qualitative inquiry, and the RCTs findings almost certainly will. From a policy perspective, qualitative insights on say barriers to participation can help inform program targeting and outreach.

In summary, this paper calls for researchers designing RCTs to consider the appropriate role of qualitative research at all stages of the study, and for qualitative researchers to see RCTs as complementary to their own research, with the two best working together. Commissioners should seek to commission more truly mixed methods RCTs, and journal editors be open to studies presenting both quantitative and qualitative findings in a single paper.

Introduction

The Delphi method entails use of a group technique that aims to obtain the most valid and reliable consensus from the panel of skillful and knowledgeable individuals by using a series of questionnaires within a controlled feedback process (Dalkey and Helmer, 1963). Delphi studies have been used in educational settings in predicting trends, standards and in forming guidelines (Green, 2014). Delphi Method works well for educator in learning experiences to prepare students for their future careers, collecting data from students and alumni regarding the curriculum and funding as they might not like to speak in focus groups, and, finally, in setting universities-wide educational goals (Green, 2014). This book chapter gives an overview of the Delphi Method and its value as a part of the mixed methods research.

Historical roots and development of the Delphi method

The Delphi method was first introduced by the RAND Corporation in the 1950s to prepare forecasts of future technological capabilities of potential interest to the military (Brown, 1968; Hsu and Sandford, 2007). The method gained popularity in the 1960s and 1970s and continues to yield solutions dealing with various problems in several diverse fields, for example, corporate management (Linstone and Turoff, 2002), information systems (Schmidt et al., 2001), E-commerce (Addison, 2003), marketing (Hayes, 2007), internet banking (Bradley and Stewart, 2003), health research (De Meyrick, 2003), and tourism research (Kaynak and Marandu, 2006).

The Delphi method has been modified over time to serve a variety of purposes such as defining a concept, setting priorities, and identifying best policies (Okoli and Pawlowski, 2004; Yousuf, 2007). Given these modifications, it is instructive to know there is a variant called Consensus Delphi, which follows the original format of the classical Delphi; there is also the Disagreement Delphi which is designed to generate discussion around topics that do not initially meet consensus (Hasson et al., 2000). These modifications¹ and different subvariants led Delphi Method to find its way into sociology, psychology, and political science.

Guiding theory and philosophy of the Delphi

Pragmatism was informed by John Dewey, who believed that social science research should focus on research objectives and problems to reflect real-world practices and decision-making (Kirk and Reid, 2002). Pragmatism is a philosophical approach that entails

¹Additional discussion of variants is offered in the "Types of Delphi Methods" subsection of this chapter.

assess in theories and beliefs based on their practical applications. The approach is based on the belief that the best research methods are the ones that help to answer the research question most effectively (Dalkey and Helmer, 1963). Pragmatism is evident in the Delphi method in the following ways: (a) The Delphi method allows researchers to use diverse approaches and valuing both subjective and objective knowledge, (b) the method is designed for practical and empirical research, (c) its findings must induce a direct influence on policy and informing practice (Alder and Ziglio, 1996).

Types of Delphi methods

Although many researchers classified the Delphi technique as a forecasting procedure, it has many other applications (Linstone and Turoff, 1975). For example, in its current application, the Delphi method was implemented to attain expert opinion, knowledge, and consensus relating to the content validity, and readability of a pool of survey and/or instrument items (Okoli and Pawlowski, 2004). There are several types of Delphi methods recognized widely by the literature:

The forecasting Delphi method

Perhaps the most basic and common Delphic exercise is the Forecasting Delphi Method, which uses numbers to estimate dates, amounts, and values. A typical example relates to Ament's (1970) long-term predictive that solicited estimates from a panel of scientists about scientific breakthroughs in biological and physical technologies, world population growth, space advances, and new weapons systems. Ament repeated this study 5 years later and found relative consistency of the forecast, shift to later median dates of many of the space forecasts and earlier dates of several biological forecasts and similar forecasting behavior as a function of median time in the future.

The policy Delphi method

Policy Delphis, unlike forecasting Delphis, produces qualitative rather than quantitative data. Policy Delphi's goal is not explicitly seeking consensus as it is to explore all the principal pro and con arguments on a particular policy issue (Linstone and Turoff, 1975). It has been used in a variety of situations, such as environmental management (Wright, 2006), social policy (Marchau and van der Heijden, 1998), and health care (De Meyrick, 2003).

The Scenario Delphi

A Scenario Delphi can be defined as a systematic narrative or description of a series of events that may occur in the future. Scenarios are forward-looking and action-oriented and often combine quantitative and qualitative data and information that describes actions over time. Each participant produces two views of the future—the probable and the preferred. One of the effective way to systematically explore varieties of possibilities in the future is the Scenario Delphi Method (Rowe and Bolger, 1991). This is because the agreements and disagreements of experts shed light on the issue under discussion and can yield alternative solutions. The Scenario Delphi typically combines two methods: (a) cluster analysis to categorize quantitative data and (b) thematic analysis to identify and interpret themes in the qualitative data (Tapio et al., 2011).

The value of Delphi technique

One of the main advantages and characteristics of the Delphi method is it affords an opportunity to gather expert input under anonymous circumstances, which can reduce the impacts of peer pressure and dominant individuals or leaders which often is a concern when using group-based techniques to synthesize and collect data (Dalkey, 1967). The anonymity issue is comforted by geographic distance and dispersion of the experts as well as the use of new technology and online communication such as social media, skype, and email to exchange and solicit data. Therefore, certain downsides related to group dynamics such as coercion or manipulation to adopt a certain perspective can be minimized.

Other merits inherent in using the Delphi Method are the ability to provide anonymity to subjects, manage a controlled feedback procedure, and the flexibility to use a variety of statistical methods for analyzing and data interpretation (Ludlow, 1975). These features in the Delphi method variant are used to minimize the shortcomings of conventional means of pooling opinions achieved from a group communication such as noise, impacts of dominant person, and group pressure for conformity (Dalkey, 1967). Noise often occurs in a group interaction that distorts the information and data and deals with personal and/or group interests instead of concentrating on solving a problem (Dalkey, 1967). Lastly, the ability to use techniques and statistical analyses tools is an exercise that further minimizes the potential of group pressure for conformity (Dalkey, 1967). Specifically, statistical analysis helps ensure agreement and consensus generated by each respondent participating in a Delphi research endeavor are well reflected in the final round (Dalkey, 1967). That is, each respondent should experience limited stress, either perceived or real, to adopt and conform to another subject's feedback that perhaps originate from obedience to custom and social values or standing within a profession.

Characteristic of Delphi variants

Number of rounds

Rounds numbers depends upon the reasonable consensus level and sufficient data and information (Delbecq et al., 1975; Ludwig, 1997). Some Delphi studies have achieved consensus after three (Brungs and Jamieson, 2005), two rounds (Robinson et al., 2005), and some others in one round (Kuo and Yu, 1999). Prior studies suggested that two or three rounds should be enough for most exploratory research projects (Skulmoski et al., 2007). Linstone and Turoff (2002) indicated a typical Delphi study will have four phases including (a) exploring, (b) understanding, (c) reasoning for differences and (d) evaluation. They believed three rounds are typically enough to achieve these goals in the general Delphi process.

The trustworthiness of the result of the Delphi method lies in its ability to draw on expertise (Miller, 2001). This can be achieved by the purposeful selection of careful selection of qualified experts for inclusion in the panel (Okoli and Pawlowski, 2004). While the term “expert” can be defined as a person with high experience and knowledge level in a specific area, the literature on the Delphi method provides many diverse ways that experts can be defined. Bowling (1997) warned that emphasis on the term *expert* may draw an individual’s attention to a person who has knowledge on the topic and is not viewed as “professionally expert.” One can however be an expert without having enough knowledge (Crisp et al., 1999). Also, selecting experts only based on their experiences may not make them an expert, as they may not possess some necessary knowledge required (Baker et al., 2006).

Although the term “expert” is not clearly defined, two key approaches have been adapted in the field to identify an expert: (a) self-assessment, and (b) sample criteria. Self-assessment relates to the evaluation of the self as an expert. The reliability of the self-assessment approach came under criticism due to inappropriate self-rating results among experts. As Pill (1971) mentioned, different people have very different ways of rating their expertise.

The second approach concentrates based on certain criteria, normally derived from the objects of the study. Numerous studies used this approach to assess the suitability of experts. For example, Simon (1965) considered the level of knowledge and experiences as criteria. For others, “expertness” is assumed based on membership of a particular organization (Snyder-Halpern, 2002) or group (Campbell et al., 2000). Therefore, the criteria for choosing experts are dependent on the purpose of the study. As noted by Goldschmidt (1975) the designer of the Delphi study must ensure that selected experts will produce much more meaningful responses than any others who fill out the questionnaire. However, there is some agreement that the expert’s “capacity” and “willingness” to participate is critical for any Delphi studies (Goodman, 1987).

Delphi sample size

In most Delphi studies, the criteria for deciding needed sample sizes are not informed by standard statistical procedures (Powel, 2003). A key point here is sample sizes should be informed by the coverage a group of experts have for a given field, the actual expertise of participants, and then consideration of agreement rates. The Delphi Method entails use of a group decision mechanism which requires group consensus toward an object and does not require the statistical sample to represent any population (Okoli and Pawlowski, 2004). If a subgroup of experts disagrees with another group, then sample size might need to be increased to better understand the phenomena of interest. Hence, sample size interacts with sample selection. Moreover, in Delphi Methodology, one is usually attempting to find experts; there will often be few such experts so randomly sampling will, typically, not be applicable (Beretta, 1996). Instead, the representativeness of the sample relates to the evaluated quality of panel members, rather than the number of experts. As such, more often, non-probability sampling techniques, including, convenience, purposeful and snowballing sampling has been implemented.

The literature on the Delphi technique does not clearly identify the sample size of the research (Adler and Ziglio, 1996). There are various opinions on the number of participants ranging from 7 to 15 (Skulmoski et al., 2007), 7 to 12 (Philips, 2000), and 8 to 12 (Cavalli-Sforza and Ortolano, 1984). The type of the sample became under close attention as criteria for sample size (Skulmoski et al., 2007). Some researcher believed a smaller group of expert panels are best fit for homogeneous groups and a larger group of experts are best suited for heterogeneous sample (Briedenhann and Butts, 2006). Since the process itself leads to attrition, Donohoe and Needham (2009) suggested starting with a larger initial panel can be useful to overcome attrition. As Garson (2014) suggested exploratory studies can use smaller panels. Martino (1972) linked the reliability of the technique with a panel of as few as 15 members. He suggested that 5 to 10 carefully selected experts could be used for a homogeneous population.

Quantitative, qualitative and mixed methods Delphi

There are many varieties of the Delphi method that range from having a quantitative orientation to a qualitative one. In the 1950s and 1960s, Delphi studies were conducted primarily by an industry to forecast dates, technological developments, and to estimate unknown parameters (Skulmoski et al., 2007) such as automated language translator, reliable whether forecast, USSR orbital rendezvous and so on. Participants generally were asked to make quantitative assessments of the issues raised. The basic assumption at hand was that a statistical aggregate of experts and skillful individuals’ judgments is more accurate than the judgment of random individuals. Despite the increased interest in using Delphi for forecasting purposes, the evaluation of the accuracy of a quantitative assessment, being a judgment method, has been problematic due to the possible influence of person- and situation-specific biases (Woudenberg, 1991). Researchers began to describe Delphi as “art instead of science.” (Murray, 1979).

In the 1970s, qualitatively-oriented Delphi approaches gradually gained increasing acceptance because of two reasons. First, the usage of the Delphi technique for forecasting has gained less attention, and focus was shifted to the communicational and educational possibilities of Delphi (Goldschmidt, 1975). Second, the evaluation of the accuracy of a quantitative assessment, being a judgment method, has been far from unproblematic due to the possible influence of person- and situation-specific biases (Woudenberg, 1991). The philosophical assumption was that the judgments cannot be measured quantitatively or equated to measurements. This led researchers to think that the Delphi method may not be fit for only quantitative application (Weaver, 1971). Later, the qualitatively-oriented Delphi found its way into the areas of public health and (Alder and Ziglio, 1996; Linstone and Turoff, 1975), and management and organizational development as a mechanism for improving the decision-making process (Hartman and Baldwin, 1995).

The broad qualitative Delphi approach was altered so that it provided several flexible techniques and analyses to interpret the judgments for consensus (Woudenberg, 1991). It can be applied in diverse situations requiring complex thinking and collaboration and to a wide range of complex problems; however, like a quantitatively oriented Delphi application, the reliability of the qualitative Delphi method was also an issue due to similar problem of person- and situation-specific biases (Woudenberg, 1991).

To overcome the reliability and accuracy concerns of any Delphi study, scholars suggested that both qualitative and quantitative perspectives should be used together, and this recommendation has been largely heeded to date (Hasson and Keeney, 2011). Nowadays, researchers believe Delphi is a mixed-methods technique in nature. As is mentioned by Critcher and Goldstone (1998), Delphi studies straddle the divide between qualitative and quantitative methodologies. There is a preponderance of studies that show the usefulness of integrating qualitative and quantitative research in a Delphi process. One mixed-methods Delphi study is Tapio et al. (2011) work involving insightful analyses of the strengths, weaknesses, and pitfalls encountered when combining qualitative and quantitative information in a Delphi process by studying seven disaggregate policy Delphi material conducted in Finland from 1999 to 2008. More recently, Taghipoorreynah and de Run (2020) illustrated the value of mixed methods Delphi in advancing the validity and reliability of an indigenous cultural values instrument. The Delphi study began with a qualitative opening round wherein the experts were asked to respond to open-ended questions concerning the indigenous culture. After generating the data input, the emphasis changed to quantitative analysis and the collection of data to achieve a consensus of the experts' opinions on the emerged values and items. At the same time, the experts were asked to respond to other open-ended questions for clustering purposes. The proposed value dimensions did not load on any quantitative or qualitative values instruments before. In each case, the mixed methods Delphi study has validated researchers' findings through integration and has enabled the understanding of a phenomenon in greater depth. This potential value makes the mixed methods Delphi a suitable tool to produce a holistic picture and to capture the internal organization of complex abstract entities.

The value of Delphi as part of mixed methods research

Improving integration in mixed methods research

The traditional quantitative vs. qualitative debates seem to have ceased recently. Instead, scholars have accepted both approaches' merits (Johnson and Onwuegbuzie, 2004). The quantitative approach assesses causes of objective knowledge or social phenomena, guided by the principle that factors, variables, and concepts should be measured by using objective research methods, rather than being inferred subjectively by using intuition, reflection, or observation (Easterby-Smith et al., 1995). The qualitative approach to research emphasizes the subjective aspects of human activity by concentrating on the meaning, rather than the measurement of objective knowledge or social phenomena (Easterby-Smith et al., 1995). On this basis, the quantitative and qualitative approaches complete each other. But the main question remains as to how researchers can use these two approaches together to gain better results instead of using them separately.

To have a holistic picture, the mixed-methods approach, in which quantitative and qualitative methods are used together, has become a more popular research approach since the 1990s (Creswell, 2008). Various concepts such as multi-method, integrated, and combined research, have been used for labeling such a methodological approach (Creswell, 2008). The main idea of the approach is to mix methods together and specify how to elaborate quantitative and qualitative elements in data collection and analyses, and explicitly explain how quantitative and qualitative aspects relate to each other (Johnson et al., 2007).

Despite the increasing interest in using mixed methods, however, the practice of integrating quantitative and qualitative methods has faced many problems. Most of the justifications for using mixed methods have not been sufficiently considered (Onwuegbuzie et al., 2011). Further, conversely, inconsistencies between qualitative and quantitative data cause unforeseen problems in interpreting research findings (Bryman, 2006).

Delphi is one of the effective methods that allows overcoming the problems in integrating quantitative and qualitative methods (Tapio et al., 2011). One well-known study in determining the value of Delphi as part of mixed methods research is that of the effectiveness of the enforcement of new international regulations on ship emissions by Bloor et al. (2015). Onwuegbuzie et al. (2011) indicated the usefulness of Delphi method as a tool for developing quantitative instruments in mixed methods research. Taghipoorreynah and de Run (2020) illustrated how using Delphi in mixed methods research can increase the sensitivity and reliability of the quantitative instruments. Torres-Alzate et al. (2020) conducted a three-round modified Delphi study using a mixed methods research approach to reach consensus among experts on global health competencies for bacca-aureate nursing students in the USA. In the first round, they revised the original list of competencies. In the second round, they conducted two surveys for the validation of the list and at the last round they conducted a survey to rate the extent to which they thought the competencies

obtained in Round Two were essential for baccalaureate nursing education in the United States. In all cases, researchers did not seek to rehabilitate Delphi as a stand-alone research method, but rather considers the possible limited role of Delphi Groups within multimethod research projects. Particularly they proposed using Delphi in the initial phase of the research can potentially serve several useful functions.

Enhancing mixed methods rigor

Given the claim that the mixed methods research combines and integrate both qualitative and quantitative methods, another approach is needed to measure rigor instead of adopting strategies that qualitative and quantitative researchers use to ensure credibility (Engels and Kennedy, 2007). According to Hasson and Keeney (2011) the term trustworthiness is more appropriate than validity and reliability to measure the appropriateness and effectiveness of a mixed methods research. Onwuegbuzie and Johnson (2006) recommended that validity in mixed research be termed legitimization to use a bilingual nomenclature that can be used by both quantitative and qualitative researchers. They indicated nine types of legitimations including sample integration legitimization, insider-outsider legitimization, weakness minimization legitimization, sequential legitimization, conversion legitimization, paradigmatic mixing legitimization, commensurability legitimization, multiple validities legitimization, and political legitimization.

Delphi enhances the trustworthiness of a mixed methods research by increasing the credibility, dependability, transferability, and confirmability (Lincoln and Guba, 1985). Delphi improve the credibility of a mixed method research by member check and feedback given to the panelist (Engels and Kennedy, 2007). It increases dependability by carefully selection and including a range and representative sample of panelists (Cornick, 2006). Delphi enhances conformability by concentrating on the accuracy at all stages of the Delphi study such as the appropriateness of the technique to address the problem selected, choice of panel members, data collection method and procedures, identification of justifiable agreement and consensus levels (Powell, 2003). It establishes transferability through the use of verification of the applicability of Delphi results (Kennedy, 2004).

Delphi also enhances legitimization of the mixed methods research through improving construct and content validity. Okoli and Pawlowski (2004) found that the Delphi method contributes to construct validity by careful research design and by pretesting. The philosophy behind Delphi technique is that group thinking can enhance content validity. The experts' knowledge and the number of successful rounds can increase content validity (Goodman, 1987). Hong et al. (2019) found that e-Delphi improved the content validity of the mixed methods appraisal tool.

Issue identification/prioritization

Using the Delphi method in the early stages of mixed methods research can help identify or prioritize the issues under study. There are several mixed methods studies in the field of Information System (IS) that have used this feature in the early stages of research to identify key managerial concerns in IS projects. For example, Lai and Chung (2002) identified a prioritized list of international data communications activities essential for multinational corporations in information exchange management to control and implement global business strategies. Scale developers also use Delphi at the early stage of research. For instance, Taghipoorreyneh and de Run (2020) used Delphi at the beginning of the mixed methods research to identify a list of values to develop instruments responsive to indigenous culture. Another example relates to Onwuegbuzie et al. (2010) work in developing quantitative instrument using mixed methods research.

Conclusion

This chapter gives researchers invaluable resources to use the Delphi method in the mixed methods research for application in educational research. The study indicates that Delphi method is the mixed methods in nature and using it as a part of the mixed methods research enhances research projects integration and rigor. Although the use of Delphi in mixed methods research may seem appealing to the educational researchers, there are some problems and limitations that need to be addressed. (1) Delphis are time-consuming. We all know that new technologies have enabled fast communication. But even if new methods are implemented in conducting the Delphi, each round can take several weeks. Because receiving information and data from experts, analyzing, and categorizing them, sending them back to receive feedback, and finally, achieving agreement requires a lot of time. This issue can be a more serious problem in mixed methods research because these methods are inherently time-consuming. (2) The technique is highly depending on to design characteristic, particularly the clarity of the research question and the level of participants' expertise. The respondents may misunderstand the brief written inputs of the moderator or research questions. (3) The experts panel might be too homogeneous or heterogeneous, therefore producing a skewed data set. (4) There is no specific criterion for measuring the level of agreement. The minimal consensus does not necessarily bring good results. (5) Delphi studies also suffer high rates of attrition. It is an iterative process which can be time consuming and therefore experts may not fully engage in the process. To reduce attrition, it is not uncommon to offer monetary incentives. (6) Finally, results are difficult to analyze and needs skill in written communication to get feedback from participants.

Glossary

Complex adaptive system A complex system with individual agents that are not fixed (i.e., individual agents that learn and adapt in response to interactions with other agents of the complex system) that defy simplistic analyses of cause and effect, where the whole is greater than the sum of its parts (Bullock, 2017; Weaver, 1948)

Complexity lens A view of how to see, understand, and influence research in which we assume nonlinearity and which is reflective of the principles of complexity science

Complexity science A collective of theories and conceptual tools used to study complex systems

Complex systems Phenomena which have the following characteristics nested structure(s) (i.e., composed of and/or comprising other complex systems), self-organizing units (i.e., spontaneously arising structures), bottom-up emergence (i.e., often surprising qualities and abilities that arise due to individual agent interactions and not over-arching governing structures), ambiguously bounded (i.e., they are open in that they interact with their surroundings), organizationally closed (i.e., they are enduringly stable even while dynamically changing), and far-from equilibrium (i.e., they do not operate in balance, rather they are continuously evolving in reaction to disturbances within and without) (Davis and Sumara, 2006). Of the two types of complex systems (i.e., complex physical systems and complex adaptive systems) the latter is relevant to the current article

Integrated findings Results that are produced by the requisite integration of qualitative and quantitative research in mixed methods designs (Poth, 2018b)

Mixed insights Also often referred to as meta-inferences, represent the interpretation of the requisite integration of qualitative and quantitative research in mixed methods designs (Poth et al., 2020)

Mixing purpose The rationale for integrating qualitative and quantitative research in mixed methods designs

Mixed methods research Research distinguished by the requisite integration of quantitative and qualitative research, and assumes that their collective contribution mitigates inherent weaknesses in either research (Poth, 2018a)

Introduction

Recognizing complexity in our educational research settings requires new ways of designing mixed methods studies. New approaches to design have arisen to address the challenges researchers face with navigating dynamic conditions in their education research settings (Koopmans and Stamovlasis, 2016). A typical response by researchers working under conditions of complexity involves attempts to reduce, control, or simply ignore its effects (Poth, 2018a). Researchers benefit from design approaches that help them conceptualize the focus of their educational research (i.e., the phenomena they are studying) to more accurately represent the dynamic realities they will need to account for in their designs. There is a pressing need for such methodological advances if we are to adequately equip researchers for studying complex educational problems using mixed methods designs. This article aims to do just that by describing and illustrating four mixed methods research design practices to address complexity in educational studies.

Mixed methods research requires the integration of aspects of both quantitative and qualitative research (e.g., data, perspectives, findings) and assumes that their collective contribution mitigates inherent weaknesses in either type of data (Poth, 2018a). For general introductions, see also the articles specific to using mixed methods in educational research (Onwuegbuzie and Marlette, Section 11) and mixed methods designs (Tajima, Section 11). The usefulness of mixed methods research for solving complex societal issues is well established (e.g., Mertens, 2015; Mertens et al., 2016; Poth, 2018a) yet researchers continue to lack practical guidance for addressing complexity and its “messiness” in educational settings. According to Plano Clark and Ivankova, the concept of messiness “recognizes the inherent complex, dynamic, and undetermined nature of mixed methods research practice” (2016, pp. 276–277). By providing practical design guidance in four practice areas, we begin to equip researchers in education with the necessary understandings and skills to make explicit their complexity-informed design decisions.

Key to the novel contribution of this article is the use of complexity science for informing the mixed methods research designs of educational settings as complex adaptive systems (CASs). Complexity science is a collective of theories and conceptual tools used to study complex systems. CAS is a complex system with individual agents that are not fixed (i.e., individual agents that learn and adapt in response to interactions with other agents of the complex system) that defy simplistic analyses of cause and effect, and where the whole is greater than the sum of its parts (Bullock, 2017; Weaver, 1948). Researchers in education need help navigating the changeable conditions that are characteristic of studies of CAS. To that end, this article offers important guidance for helping researchers manage their mixed methods research designs to assimilate emerging understandings of the educational CAS studied.

The impetus for this article was the lessons that emerged from our joint reflection upon our experiences and their potential usefulness for others. In this work, we were building upon the initial descriptions of six adaptive design practices by Poth (2018a), the conceptualization of educational research teams as CAS (Poth, 2019), and Bullock’s innovative practice transformations for addressing complexity in education (Bullock, 2017). The details of these previous works are not important because just like CAS, our own thinking and practices have since evolved. Importantly, while we are not alone in our use of complexity science to frame educational phenomena as CAS (Davis and Samara, 2006; Jacobson et al., 2019; Koopmans and Stamovlasis, 2016), its nascent application to mixed methods research holds great promise and warrants attention (Kallemeyn et al., 2020). Our novel contribution in this article involves providing practical design guidance for mixed methods researchers to address complexity in education in a way that is accessible to a range of expertise in mixed methods research (i.e., from newcomers to established experts).

This article shows you how to transform mixed methods research design practices to address complexity in education by focusing on four areas of design decisions and their unique contributions to making explicit the point(s) of integration, defining the perspectives and contexts captured by the study, type and sequencing of data procedures, and accounts of how the outcomes were derived. To help researchers bridge theory and practice, we will interweave discussions of two published mixed methods study examples from our own work. Key theoretical and practical implications of the design conclude the article with guidance for managing the complexity inherent in educational settings and study designs. We begin with an orientation to situate the reader to complexity theory in education and mixed methods.

Situating complexity science in education and mixed methods research

Many of society’s most pressing and pernicious social problems involve multiple, interacting influences with no known solution or established methods and expertise for studying the interrelated and dynamic contexts in which they take place. Thus, it is logical that novel solutions to such societal problems are likely to be derived from interdisciplinary perspectives and methodological innovations. A growing body of literature explores the intersections and yet unrealized potential of complexity science, educational settings, and mixed methods research (e.g., Kallemeyn et al., 2020; Poth, 2018a,b). As a theoretical framework, complexity science can provide important guidance to study CAS encountered by educational researchers. Studying educational CAS requires us to reconsider our assumptions about the stability of the research conditions and transform our research design practices accordingly. Complexity science as an ontology or theoretical frame of reference for research on, or within, educational settings offers an alternative to understanding phenomena by examining its parts by instead focusing on organic and holistic systems and their interactions (Lewin, 1993). Complexity-informed research and clinical practice transformations are occurring across diverse disciplines (e.g., business, evaluation, and health).

Using a complexity lens to inform mixed methods practice offers researchers a better way to make sense of the realities of educational settings and transform their approach to research design, making it more realistic. Among the key benefits for mixed methods researchers of complexity-informed approaches is their increased capacity to appropriately respond and adapt design practices to evolving conditions (Poth, 2018a,b). Understandably, this thinking permeates the mixed methods research process from initial conceptualization of the design to data collection, analysis, and integration as well as the reporting of study outcomes.

Kallemeyn et al. (2020) conceptualized four ways of thinking about complexity theory and its implications for mixed methods research: (1) describing complexity theory as an alternative paradigm to scientific inquiry, (2) applying complexity theory to the study of complex systems, (3) using complexity theory as a theoretical framework, and (4) treating the field of mixed methods as a complex adaptive system itself. We agree with our colleagues that these conceptualizations of complexity theory and mixed methods research point to a “mutually informing relationship between study phenomena and methods” (Kallemeyn et al., 2020, p. 289). Furthermore, similar to Byrne and Callaghan (2014), we recognize that the state of the field is such that there are not yet well-defined and well-prescribed methods for conducting research through a complexity-informed lens. It is with this article that we contribute important methodological advancements for approaching the design of studies in education informed by complexity science to more accurately study educational institutions and settings as the interrelated and dynamic contexts that they are.

Illustrating four mixed methods research design decision transformations

To learn how to approach the design of CAS informed by complexity science can be challenging, yet examining real world dilemmas and opportunities can provide a logical starting place. In the following sections, we use two published mixed methods research studies from our own programs of research to illustrate the contributions of four complexity-informed design decisions to the mixed methods research process. Through the lens of complexity theory Bullock (2017) study sought to explain the role the school leader plays in students' mathematics achievement by integrating survey data and focus group interviews. Through applying a systems perspective Poth et al. (2020) conceptualized the doctoral course in which the learners were enrolled as a CAS to generate a more complete understanding of the impactful experiences learners attributed to their competency gains by integrating existing qualitative and quantitative data from course artifacts.

We noted in our reflection that both the commonalities and differences between our studies were worthy of attention: First, both studies took place in educational settings and benefitted from conceptualizing the interrelated and dynamic contexts as CAS. Second, each of the studies drew upon different data source combinations to generate novel understandings that could not be accessible by either qualitative or quantitative research alone. Third, as we each grappled to make explicit our design adaptations, we came to use the metaphors of braiding or twisting to describe how our decisions were interwoven in often unexpected, non-linear, and changeable ways. It is our hope that by reading about two distinct studies, researchers can imagine the infinite possibilities that exist for their own work.

We organize our descriptions of our unique complexity-informed approaches by four interdependent design decisions visually represented in Fig. 1: Initial design decisions, evolving data decisions, ongoing analytical decisions, and authentic reporting decisions. Each of the four descriptions of the mixed methods research design decisions makes explicit its unique contribution to the mixed methods research process, the opportunities of CAS conceptualization to the mixed methods research process, and the practical guidance afforded by the mixed methods research design practice transformation for researchers (see Table 1 for summary).

Representations of the nested structure of CAS informs initial integration decisions

The need for integration, often represented by a mixing purpose statement, is essential to determine if mixed methods research is a suitable approach for the study (Creswell and Plano Clark, 2018; Poth, 2018a). The nested structure of the CAS can help researchers relate the point(s) of integration appropriate for addressing the study's mixing purpose by identifying the unit of analysis. We operationalize a unit of analysis as the focus for the requisite integration for a mixed methods study. When a researcher conceptualizes their study context as a CAS, they intensify the need for appropriately identifying the unit of analysis within the

Fig. 1 The braiding of four key design decisions when conceptualizing educational study contexts as CASs.

Table 1 Four key mixed methods research design decisions and complexity-informed practice transformations.

<i>Mixed methods research design decisions</i>	<i>Unique contribution to the mixed methods research process</i>	<i>Opportunities of CAS conceptualization to the mixed methods research process</i>	<i>Guiding mixed methods research design practice transformations</i>
Initial design	Identification of unit of analysis	Relates point(s) of integration to guide the study	Represent the nested CAS structures
Evolving data	Selection of data sources and sampling	Defines the perspectives and contexts captured by the study	Attend to the dynamic CAS interactions
Ongoing analytical	Description of integration procedures	Describes the type and sequencing of data procedures	Adapt to emergent CAS conditions
Authentic reporting	Credible interpretations	Explains how outcomes were derived	Convey transparent accounts of CAS studies

nested and interdependent systems. Sound near impossible? How is this done? Several options exist for units of analysis within CAS found in educational institutions and settings and distinguishing among the embedded levels can be challenging. For example, at the level of a school, the agents consist of stakeholders (e.g., administration, teachers, parents, students) which are influenced by—and in turn, influence—a set of initial conditions (e.g., demographics, school setting, teacher quality, supports for teachers, supports for students, school schedules, data usage). These agents are all dynamically and continuously changing and adapting as different stakeholders move in and out of the system or exercise their individual agency, interact with, and influence each other. This system of the school, as a whole, undergoes an emergent process in which phenomena like school culture, academic learning, and traditions constantly evolve, moving in measurable trajectories which can follow predictable patterns as groups within the system continuously self-form and interact with each other.

To illustrate what we mean by nested structures in educational settings, while an individual school may represent the whole of our CAS, we know that there are influences on that nested system from larger CASs such as districts and states (or border regions). Within the nested structures, the individual school is an embedded complex agent (Jacobson et al., 2019) and is both influencing to and influenced by smaller CASs within an individual school such as grade level cohorts, individual classrooms, and even individual students (Pennings and Mainhard, 2016; van Vondel et al., 2016). Fig. 2 represents this nested structure to help researchers

**Fig. 2** A visual representation of nested structures within CAS for guiding the selection of the unit of analysis for the study.

distinguish among the larger and smaller CASs to identify their unit of analysis for the initial mixed methods research design decisions. The zoomed-out graphic on the right (labeled C) represents the larger CAS such as a school or institution, whereas the smaller zoomed-in graphic on the left (labeled B) represents the nested systems such as an individual class or an individual stakeholder. It is also possible that the larger CAS is part of an even larger CAS, such as schools that are part of the same district. By distinguishing the nested structures involved in your study helps identify the unit of analysis you intend to study. It may be that researchers are trying to decide which nested system to focus on which is where the interdependencies among the decisions exist—perhaps looking at the data sources (see next section) can help researchers. We recommend that newcomers to mixed methods research focus on a single unit of analysis whereas more experienced researchers may decide to focus on more than one.

You might now be asking, “How does identifying the study’s unit of analysis within the context of a CAS help inform the initial design decisions relating points of integration?” If we look at our two studies; we see the nested structures for each of our studies in our visual representations similar to Fig. 2. For Bullock’s (2017) study in Fig. 3, we see that the smaller CAS (labeled B) represents the principal’s school as nested within the larger CAS (labeled C) representing the school district. If you remember the study purpose was to explain the role the school leader plays which suggests the point of integration for this study was school principals as the unit of analysis. Conceptualizing the study as a CAS allows the identification of the unit of analysis at the individual level of a school principal (labeled A) within the context of their school’s complex initial conditions (labeled B) and intertwined with the various stakeholders within the school district system (labeled C) to more authentically predict and explain the emergent property of school-wide student mathematics achievement. With the selection of the individual principals as the unit of analysis, Bullock could focus on collecting both quantitative and qualitative data sources to generate a more complete understanding of the influences on, and by, the principal within the CAS of their particular schools to explain the principals’ role in promoting student mathematics achievement. Together these emerging understandings of the unit of analysis of the school principal helped Bullock to consider the data collection sequencing as appropriate for her explanatory-focused mixing purpose of the role of the school leader.

In contrast, in Poth’s et al. (2020) study in Fig. 4, we see that the smaller CAS (labeled B) represents the doctoral class as nested within the larger CAS (labeled C) representing the university. If you remember the study purpose was to generate a more complete understanding of the competency gains learners in the class reported through the integration of descriptions of impactful course experiences which suggests the point of integration for this study was the class as the unit of analysis. Conceptualizing the study as a CAS allows the identification of the individual learners (labeled A) as nested within the unit of analysis at the group level of the class (labeled B) and intertwined with the various stakeholders within the university system (labeled C) to more authentically

Fig. 3 A visual representation of nested structures within CAS for Bullock (2017).

Fig. 4 A visual representation of nested structures within CAS for Poth et al. (2020).

predict and explain the emergent property of increased gains in competency. With the selection of the group of learners as the unit of analysis, Poth could focus on collecting both quantitative and qualitative data sources to generate a more complete understanding of the influences on, and by, the individual learners within the CAS of their particular course to generate understandings of the impactful experiences the group of learners attributed to their competency gains. Together these emerging understandings of the unit of analysis of the group of learners helped Poth to consider the use of a case study as appropriate for her completeness-focused mixing purpose.

As we reflected on our unit of analysis decisions, we found that recognizing how we focused our studies as situated in the broader CAS structure was helpful. Yet we have also come to realize that pre-determining the unit of analysis within a CAS can be especially challenging because of the fractal and dynamically changing nature of CASs. Common to both our approaches was the decision to represent the people involved as influencing and being influenced by their surrounding conditions. For Bullock, it was the influences of the many different stakeholders within their specific schools as well as the district, state, and national contexts in which the school was embedded. For Poth et al. (2020), it was the influences of the many contributors to the group of learners in the class, as well as the instructional, institutional, and societal contexts in which the course was embedded. Interestingly, we realized that our familiarity with our study contexts from past instructional experiences meant that neither of us experienced challenges in identifying our unit of analysis at the beginning of our studies. When studying CAS using mixed methods research in educational settings, we found transforming our practice to represent the nested structures helped identify possible units of analysis for guiding where the points of integration might take place. Thus it becomes clear, but only rather implicit, that the choice of unit of analysis for the study is intertwined with data source decisions (Fig. 1) because the perspectives that have an influence on the unit of analysis are key data sources.

Attention to interactions of the CAS informs data source and sampling decisions

The justification of data sources is essential for planning mixed methods research and has important implications for defining the perspectives and contexts captured by the study (Poth, 2018a). We use sampling strategies involved in qualitative and quantitative research as well as ones that address relationships across the research samples, sometimes referred to as the mixed sampling strategy (Onwuegbuzie and Leech, 2007). For an overview of mixed methods sampling and data collection see also the article offered by Leech and Donovan (this Section). When a researcher conceptualizes their study context as CAS, they highlight the need to consider

the interactions among the multiple and interrelated levels influencing the selected unit of analysis because the behaviors of the systems may not yet have been studied or even identified. Determining appropriate data sources and sampling plans for the interactions within a unit of analysis is challenging because individuals can be associated with multiple groups within a level or even across levels. This can lead to groupings of individuals which are not independent, with important sampling and statistical implications.

Within educational settings, while data are collected for individuals, we know that the individual is both influencing and being influenced by the larger system as well as by the individual's previous experiences. Collecting data at one time point or perspective may or may not be sufficient to accurately represent the system's behavior and address the study need for integration. Fig. 2 presents possible interactions within systems. The zoomed-out graphic on the right (labeled C) could represent the larger CAS such as a school or institution, whereas the smaller zoomed-in graphic on the left (labeled B) could represent the individual class or an individual stakeholder. As before, it is also possible that the school is part of an even larger CAS, such as a district or educational system which also requires data collection. Focusing attention on the interactions provides researchers with important information for determining appropriate data sources and sampling.

You might now be asking "How does attention to the interactions help identify appropriate data sources to inform sampling"? If we look at our two studies, we see that in Bullock's (2017) study, attention to the possible interactions involved in the CAS required multiple levels of data sources to be collected over several months and that researchers build upon emerging understandings of the unit of analysis. The initial data collected involved a survey via census sampling, with questions for the school leader (labeled A in Fig. 3) addressing a total of 193 possible characteristic variables. Quantitative analytical techniques allowed Bullock to recognize characteristics of school principals which predict students' mathematics achievement (and whether these variables were independent, or not) and determine the most important relationships between those characteristics and the dependent variable. Bullock then utilized maximal variation sampling to select appropriate focus groups to qualitatively explain the influential stakeholder relationships for the school leaders' decisions and actions involving those most important characteristics across CASs (those labeled C and higher levels beyond in Fig. 3). Integrating the two data sources generated novel descriptions of emergent properties that were otherwise obscured; these related to how school leaders' decisions and actions were associated with students' mathematical achievement (labeled B in Fig. 3).

In contrast, while Poth et al.'s (2020) study focusing attention on the possible interactions involved in the CAS also required data from multiple levels, the data sources and sampling were vastly different. Of particular importance to Poth's study was capturing both the individual (labeled A in Fig. 4) and the group of learners (labeled B in Fig. 4) as well as their collective interactions and outcomes in a way that went beyond the simple recollection. Her use of individual and group course artifacts—including pre- and post-course ratings and narratives generated throughout the class, along with instructional documentation and an end-of-course focus group—generated numerous data points contributing to the rich case description which would have been inaccessible by either qualitative or quantitative data sources alone. All those involved in the study were invited to participate; this yielded matched data from the group of 11 learners enrolled in the class.

As we reflected on our data sourcing decisions in both studies, we discovered that recognizing the focal interactions and assessing the extent of independence of agents for our study was helpful in determining appropriate sampling. Yet we have also come to realize that pre-determining the interactions within a CAS and selecting sampling strategies can be especially challenging with sequential designs because of the emergent nature of the interactions. Common to both studies' approaches were multilevel data sources, sampling suitable for our mixing purposes, and understandings that emerged over time. Bullock had tried to determine overlapping group memberships of her unit of analysis. In her reporting, she justified the independence, or lack thereof, of data sources and selected sampling dependent upon the outcome. For Poth, a convenience sample was appropriate for including all those involved in the course. When studying CAS using mixed methods research in educational settings, we found transforming our practice to attend to the dynamic CAS interactions helped identify possible data sources and samples for capturing the various contexts in which interactions occurred. Thus it becomes clear, but only rather implicit, that the choice of data sources and study samples is intertwined with integration decisions (Fig. 1) because the samples that have an influence on the integration are key to generating relevant insights addressing the mixing purpose.

Adaptations to emergent CAS conditions inform integration procedural decisions

Adaptations to integration and analytical procedures are required in mixed methods research, yet rarely are rationales provided in sufficient detail to inform future researchers' appropriate responses to emerging study conditions (Poth, 2018a). What adaptations are made and why has important implications for when and how integration will take place to realistically represent the complexity inherent in education and, ultimately, the complexity in point(s) of integration and procedural descriptions. When conducting research, we conceive of emergent conditions as those that are nonlinear and changeable in unpredictable ways as well as those that may be linear and more predictable. Points of integration are where we find the "*purposeful interdependence* between different sources, methods, or approaches" (Bazeley, 2018, p. 7, italics in original). When researchers conceptualize their studies as CAS, they intensify the need to adapt to emergent conditions in ways that allow integration to generate understandings of the whole that are greater than the sum of its parts (Fetters and Freshwater, 2015). The integration of qualitative and quantitative data provides opportunities through which we can more accurately understand the emerging properties of the phenomena.

Complexity science guides educational researchers in considering the dynamic and nonlinear aspects of CAS in addition to accounting for many possible independent and not-so-independent variables which impact the dependent variable. Byrne and

Callaghan's (2014) argument about the important distinctions between restricted complexity and general complexity provide important guidance. Whereas "restricted complexity" results from interactions at simpler levels only and thus allowing for known quantitative modeling techniques, "general complexity" results from nested interactions that allows for quantitative modeling of individual agency. What is noteworthy about their work, which remains in its infancy, is that the "general complexity" represents what Bryne and Callgahan describe "interpenetrating systems with causal powers running in all directions" (2014, p. 45). If we adopt this perspective of "general complexity," those studying CASs must carefully consider the most appropriate integration and procedural decisions and adapt their initial research design appropriately for emergent conditions.

You might now be asking, "How does adaptation to emergent conditions support integration and inform appropriate procedural designs?" As we reflected upon our two studies, Bullock noted that she had paused her study after the initial quantitative analysis to refine her qualitative data collection procedures and rethink the points of integration. Importantly she described having shifted from an originally conceived linear explanatory sequential design (See Fig. 5) to one that was implemented to incorporate opportunities for further integrations (see Fig. 6). The implemented design is considered less linear than the original design because the bidirectional arrows represent opportunities she took to revisit phases in the research to assimilate emerging understandings of the study CAS. Bullock justified these adaptations as a way to better understand the influences on, and from, the school leader—a way to account for the overlap between individual agency in decision making and stakeholder influences.

While the adaptations in Poth et al.'s (2020) study also involved rethinking the points of integration, she noted that the refinements had been focused on the case analysis procedures. She described the need to expand the scope of integration; whereas she had initially planned to integrate on only one construct of instructional experiences. However after attending to the emerging understandings, the integration was instead focused on three constructs. Poth justified these adaptations as a way to generate more nuanced descriptions of the outcomes emerging not only among learners but also emerging in their engagement with the course instructor and guest speakers. Thus the points of integration in this case became focused on the instructional, relational, and personalized experiences of the learners. Working through a complexity lens allows researchers to acknowledge the messiness inherent in studying CAS and to adapt their procedures as new information comes to light.

As we reflected on our integration decisions in both studies, we found it helpful to recognize what understandings emerged while studying CASs. Yet we have also come to realize that predetermining suitable integration procedures can be especially challenging because of the evolving nature of the surrounding conditions. Common to both study's approaches was a point at which researchers stop and reconsider initial procedural design decisions in light of emerging understandings. For Bullock, it was the stakeholder influences and their resulting impacts on the school leader's decisions that warranted further attention. For Poth, it was the instructor and guest speaker influences and their resulting impacts on class learning outcomes that warranted further analysis. Interestingly, we realized both from our own experiences and from those of our colleagues and students that procedural adaptations are much more common than study accounts portray. Research accounts must carefully consider and describe why and how adaptations are justified by the researcher. When studying CAS using mixed methods research in educational settings, we found transforming our practice to adapt to emerging CAS conditions helped generate descriptions of integration procedures that were more realistic. Thus, it becomes clear, but only rather implicit, that the description of integration procedures is intertwined with credible interpretations decisions (Fig. 1) because the procedures that have an influence on the integration are key to methodological transparency.

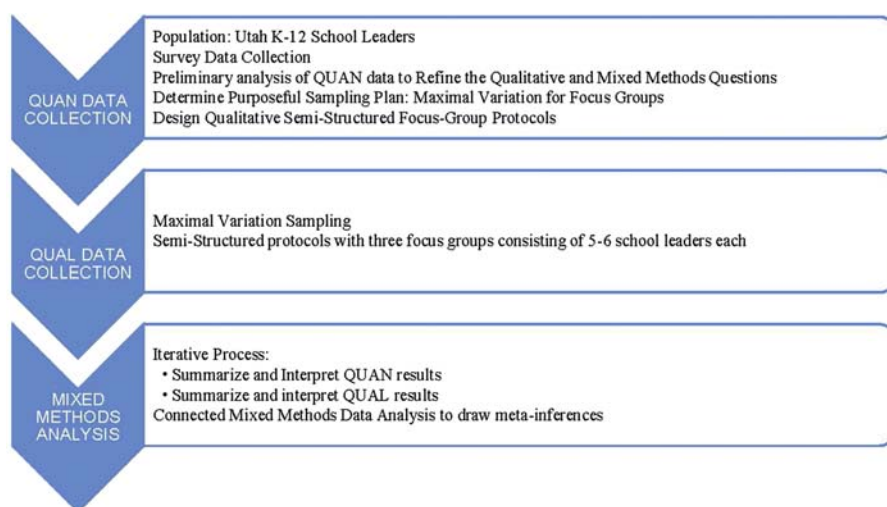

Fig. 5 Originally conceived linear explanatory sequential design for Bullock (2017).

Fig. 6 Implemented less linear explanatory sequential design for Bullock (2017).

Transparency of accounts of CAS outcomes informs credible interpretation decisions

A key responsibility for any mixed methods research account is to demonstrate methodological transparency to the extent possible. For mixed methods research it is particularly important to present evidence of its key characteristic of integration. In practice, we consider evidence of methodological transparency to involve descriptions of the study's need for integration, procedures, and insights generated from the integrated findings. Methodological transparency has emerged as a key quality indicator in mixed methods research (Cain et al., 2019; Levitt et al., 2018; Onwuegbuzie and Poth, 2016). For a primer on quality in mixed methods research see also the article by Collins (this Section).

When studying educational CAS, predetermining study outcomes is challenging because of the lack of certainty and the inter-connecting and changing nature of CAS. Thus, when we study CAS in educational settings we must authentically report our methods in ways that provide evidence of methodological transparency specific to mixed methods research. Every effort to document and justify our integration and analytical decisions is as important as reporting our findings and discussing their implications, for our findings and implications depend on those decisions.

For complexity-informed mixed methods insights to be considered credible beyond the local, we have to recognize that the localization of our findings constraints how we may talk about causality or transferability. In CAS, causation can be best understood through the comparison of differences across cases which allows researchers to use these differences as a way of guiding action to achieve outcomes (Byrne and Callaghan, 2014). This has huge implications for mixed methods researchers as we provide authentic accounts of how we operate under conditions of complexity (Poth, 2018a; Poth et al., 2020). Researchers commonly report their procedures as if no adaptations took place. The result is underreporting of adaptations that researchers make. Detailing the messiness in adapting research plans and reports is appropriate and necessary when studying CAS because researchers need to recognize and respond to "the inherent complex, dynamic, and undetermined nature of mixed methods research practice" (Plano Clark and Ivankova, 2016, pp. 276–277).

You might now be asking, "how does the transparency of accounts of CAS outcomes inform the authentic reporting decisions?" In our two studies; we see that Bullock's (2017) study used visualizations in addition to narrative descriptions to convey her interpretation processes. These visualizations shed light on how she mixed quantitative and qualitative analyses and what the analyses contributed to the overall mixing purpose. Similarly, Poth et al. (2021) used a procedural figure to convey the processes involved in the initial separate analysis of qualitative and quantitative data and then how those findings were integrated using a qualitative-dominant cross-over mixed analysis approach to generate the four mixed insights for the study. A qualitative-dominant cross-over mixed analysis involved using the qualitative themes as the organizational framework on which to integrate the

quantitative data (Onwuegbuzie and Hitchcock, 2015). A procedural visual helped make explicit the interpretation processes to provide evidence of reasoned insights.

As we reflected on both our research studies, we found that being explicit about how our mixed insights had been generated from the study of CAS was helpful to contribute evidence of our reasoning. Yet we have also come to realize that pre-determining the necessary evidence of integrity for the study of CAS can be especially challenging because of the yet-to-be-known emergent study properties and outcomes. Common to both study's approaches was representation of the processes involved in the inference-generation procedures as influencing and being influenced by the data interpretations. Bullock was explicit about the iterative influences of the multilevel data samples on the emergent analytical procedures which led to emergent insights. Poth was explicit about how the insights relating the collective experiences which learners attributed to their course outcomes were different from what could have been measured from individuals' data alone. Interestingly, both realized that their comfort with research messiness from previous research experiences meant that neither assumed the interpretation processes would be straightforward. When studying CAS using mixed methods research in educational settings, we transform our practice by identifying possible interpretations and seeking purposeful evidence of integrity to inform the study's results decisions.

Implications for complexity-informed mixed methods research in education design practices

To support mixed methods researchers in managing the complexity inherent in educational settings and problems, we now advance key theoretical and practical implications of the design guidance. Together, the discussion of complexity-informed mixed methods research design practice transformations, the generation of practical insights for navigating the challenges faced by researchers studying CAS, and the lessons gleaned from a reflection of two authentic accounts realizes an important aspect of the methodological advancements described in the Future of Mixed Methods Task Force report (Mertens et al., 2016).

Our discussions and illustrations of complexity-informed mixed methods research design practice transformations advances our theoretical understandings of the realworld applications of the four design decisions summarized in Table 2. In so doing we recognize the key contributions of four designs decisions which serve as indicators of complexity-informed mixed methods research quality (e.g., Fàbregues and Molina-Azorín, 2017; Creamer, 2017; Onwuegbuzie and Poth, 2016). Our reflection upon our experiences has yielded important insights about the challenges researchers must navigate when studying CASs. In doing so, we extend Kallenmeyer's theoretical conceptualization of a complexity lens onto mixed methods research design practice. The comparison of two published studies provided both illustrative examples of vastly different studies of CASs in education and essential lessons for others to be guided by and extend in the future. Our accounts also advance the use of authentic accounts of complexity-informed mixed methods research practices for others to learn from (Poth, 2018a).

Concluding thoughts

Our impetus for this work was the lack of practical guidance we could find as we were engaging in addressing complexity in education in our own studies. Only later could we articulate the source of our challenges as the complexity inherent to our studies and how we had transformed our practices to manage. Over the last few years we have been encouraged to confirm that the work we

Table 2 Summary of four key mixed methods research design decisions and complexity-informed practice transformations.

<i>Mixed methods research design decision and unique contribution</i>	<i>Key design practice transformations</i>	<i>Complexity-informed mixed methods research design practices</i>
Initial design decisions involve identifying the unit of analysis	Represent the nested structure of the CAS to focus the study on the appropriate point(s) of integration	Distinguish among the embedded levels of the CAS Select a suitable unit of analysis for the study's need for integration
Evolving data decisions involve selecting data sources and sampling	Attend to the dynamic CAS interactions to define the appropriate perspectives and contexts captured by the study	Determine appropriate data sources for the unit of analysis in the CAS Distinguish suitable data sources for the study's interactions
Ongoing analytical decisions involve describing the integration procedures	Adapt the procedural decisions to respond to emerging CAS conditions and respond to the study's mixing purpose	Describe appropriate integration for the multilevel data collected within the CAS Distinguish suitable adaptations for the study's integration procedures
Authentic reporting decisions involve accounting for credible interpretations	Generate transparent accounts of how the interpretations were generated from the findings	Report appropriate evidence of integrity for the emergent conditions of the CAS Distinguish suitable evidence of validity for the study interpretations

engaged in was innovative and we share our lessons learned here for the benefit of readers. We encourage others to do the same. Our collaborative work on this article reflects the forward thinking necessary for managing the complex conditions surrounding many pressing societal issues and was informed by our own research experiences and the experiences of others around us and as authors, reviewers, and readers of mixed methods research literature.

Acknowledgments

The article advances new insights and extends ideas we have previously published separately (e.g., Bullock, 2017, and Poth, 2018a,b, 2019). We thank Adrienne Montgomerie and an anonymous reviewer for helpful comments on the draft manuscript. We are grateful for the opportunity to contribute to this encyclopedia and thank our colleagues from around the world who continue to influence our thinking as well as our Volume editor Dr. Nataliya Ivankova and the editors-in-chief for guiding this article through to publication.

Introduction

The implementation of mixed methods research practices in various academic fields has gained vast popularity in recent decades. It is argued that mixed methods research has a great potential to contribute in uncovering the challenges and offering solutions to important and complex societal problems (Mertens et al., 2016). In the field of education, the universities and funding agencies have encouraged research that addresses broad and enduring problems of education in an increasingly diverse and unequal society. Such large-scale research is best served by research teams drawn from different disciplines and combining a wide range of research designs and methods (Weis et al., 2019). Commonly this kind of research practices are called as “multimethod”, “multiple methods” or “mixed methods” research (Niglas, forthcoming). We choose to follow the call of the MMIRA task force welcoming flexible and open methodological framework and using “mixed methods” (MM) as the general term for the tradition (Mertens et al., 2016), because the concept of MM is widely used in the broad interdisciplinary field of education.

Recognizing that often MM is about combining qualitative and quantitative methods and methodologies, we purposefully adhere to the broad definition of MM suggested in the abovementioned report: “use of more than one method, methodology, approach, theoretical or paradigmatic framework” and “integration of results from those different components” (Mertens et al., 2016a, p. 4). Our stance, looking at MM more broadly than specific tool used to collect information, is congruent with the ways the group of influential scholars in education have conceptualized this methodological tradition:

We thought of “mixed methods” as encompassing broad uses of research concepts, theories, designs and methods drawn from a wide range of disciplines, intellectual traditions, and research paradigm; as dynamic and integrated uses of methods that complement one another as they unfold over time and across levels and scales of a system; as guides to more comprehensive studies; as ways to collect, analyse, and integrate data creatively; and as ways to interpret and disseminate results to a wide range of audiences.

Weis et al. (2019).

We recognize the important contribution that the authors around the globe have made in developing the scholarship and awareness of MM research designs (see for example Niglas, forthcoming for concise overview). However, the field is still in the phase of fast development and there is a need for further insights from specific disciplinary and methodological point of views. We take special focus on large-scale MM studies as this seems to be the gap in the current methodological discourse.¹ Therefore, our modest contribution in the first part of this chapter provides a concise overview of the literature on the challenges that the teams of the large-scale MM studies in the field of education are facing and need to unriddle.

In the second part of the chapter we build on the results and experiences from our recent large-scale MM research project focusing on the vital influences that the teachers’ professionalism and national educational trajectories have on the global policy transformations and related educational reforms.² Our exemplary study focusses on Estonia, but helps to shed some light to the broader context of fundamental education change that followed the regime change in post-socialist countries. By tackling how global initiatives are modified, redirected and potentially transformed across different spatial and temporal contexts and across various societal

¹The concept of a *large-scale empirical study* is most often used in connection with survey research where the number of the participants or subjects, representing the population, is high. Typically surveys with a sample size ca 1000+ could be considered large-scale. In the MM context the concept of large-scale study has more dimensions and the sample size does not always play a pivotal role. Instead, the complexity of the MM design (incl the number of combined methods and the depth of integration) can determine the need for multiple and/or multilevel data collection phases, prolonged intensive study period and a large research team with diverse competences and experiences.

levels our research helps to understand the reasons of the widespread failure of educational change initiatives and finding ways to better support teachers' professionalism.

While providing pool of internationally relevant and thought-provoking results we, as a team of the large-scale MM research project, had to find solutions to a number of methodological and practical challenges. In an earlier paper we reflected on the issues of the team dynamics in the context of non-hierarchical shared leadership model that we implemented (Niglas et al., 2018). Our further insights provided in this chapter demonstrate, that the integration of the data and findings from different stages of the sequential MM study and especially MM publishing are the central issues that need careful attention by the large-scale MM research teams.

Challenges in conducting large-scale MM studies in education – the literature review

The mixed methods research community has provided important scholarly discussions and produced a vast pool of theoretical as well as practical knowledge to guide designing and implementing of MM studies (Niglas et al., 2018). However, limited attention has been paid to the ways in which MM can be thoughtfully and rigorously employed to tackle the broad and enduring issues in the field of education. To address this limitation the US based Mixed Methods Working Group (MMWG) sponsored by Spencer Foundation was convened in 2014 with the aim to provide guidelines for broad-based MM research projects that address significant research questions in education by capitalizing on the complementary strengths of different methods (Weis et al., 2019).

The MMWG emphasized the need to move beyond the “qualitative-quantitative binary” when designing educational studies. This means one should keep in mind that methods are not independent of the disciplinary and theoretical traditions and choose the research methods that best serve the research questions at issue (see also Bowers et al., 2013; Creswell et al., 2011; May and Burke, 2010). Working group saw fruitful combinations, integration and iteration as the key features of effective MM research. Using various methods and techniques like experiments, surveys, ethnographic observations, in-depth interviews, etc. is a well-established practice in education research. When combined effectively, the complementarity of the methods can help to deepen understanding of the studied phenomenon, but also challenge one another illuminating taken-for-granted assumptions or initiating new insights (Weis et al., 2019).

The need to integrate, coordinate, iterate, or juxtapose the data and findings from different methods within a large-scale educational research project demands a high level of team interaction and shared attitude of methodological and theoretical flexibility. Constituting and managing the MM research team is posing a challenge that the leaders of large-scale studies or programs of study need to face and successfully resolve (Bowers et al., 2013; Creswell et al., 2011; May and Burke, 2010). Researchers from the field of health sciences have provided valuable suggestions for establishing practices that help to solve emerging difficulties when managing MM teams (e.g., Bowers et al., 2013; Hemmings et al., 2013; Robins et al., 2008).

To unravel the potential conflict among differing epistemological standpoints or colliding worldviews, disciplinary- and paradigm-level borders need to be converged before a MM team can effectively operate (see Johnson, 2017 for the useful discussion). As maximizing the qualitative contribution has been experienced often as a challenge for MM teams, qualitative experts should be involved in the design as well as the execution of the MM study as early as possible (Robins et al., 2008). On the other hand, it is important to realize that researchers bring their home group (i.e. organizational, professional, and other representational groups) identities to the new group (Curry et al., 2012; Hemmings et al., 2013). Thus, the convergence and operation as one team inevitably involves working outside of one's comfort zone (May and Burke, 2010).

Successful leaders for MM teams should be able to overcome and bridge differences and create an effective working environment. This can be achieved by keeping an open dialogue going within the team and by taking into account team members' responsibilities outside the project while being concrete about their roles and duties inside the team and also promoting collaborative relationships among team members (Creswell et al., 2011; Curry et al., 2012). Bowers et al. (2013) argued that in MM research study, a non-hierarchical, shared leadership model might be needed for implementing the full potential of the team. In this model, all activities (e.g. resource allocation and sharing, project and measure design, data collection, analysis, interpretation, dissemination) require collaboration by and active engagement of every member of the research team. To meet the challenges that they faced in an exemplary THRIVE project, the Coordinating Center and various regular meetings were established in order to introduce relevant literature and theoretical-methodological approaches to the members of the team with different disciplinary and methodological backgrounds, as well as to support the commitment of the whole team.

Practical challenges related to the team dynamics were thoroughly tackled in the chapter reflecting on the experiences of the research team with a non-hierarchical shared leadership model conducting a large-scale MM program of study in education (Niglas et al., 2018). The analysis demonstrated that team members brought into the project different home group identities and experiences even though they came from the same broad discipline of education. This, in combination with a multilevel leadership model, seemed to result in the varied interpretations of the conceptual and methodological aspects of the study within different work-groups. We learned that a fine balance needs to be found between the autonomy of the work-groups and centrally facilitated construction of a shared conceptual framework.

Also, ongoing communication and collaboration among all team members (within workgroups and across workgroups) as well as the establishment of clear communication patterns to produce the functioning networks are important for project success. Communication should include learning about the competencies of all members of the project and also understanding and adopting of project leadership roles and activities. Successful leadership of large research teams requires an awareness of the consequences

of practical issues such as being paid directly from the project or not, agreeing about the allocation of project work, balancing the duties and commitments the team members might have outside the project, and so forth, because these issues significantly impact the commitment of team members (Niglas et al., 2018).

May and Burke (2010, p. 3) emphasize that issues around analyzing, interpreting, and integrating different data may pose a key problem even if the “creative, intellectually-challenging-yet-supportive team” has been formed. The MMWG pointed out the challenge of supporting the professional identity building for MM researchers, referring to the researchers who have the training and ability to work on MM teams, but assumed that up to date majority of scholars are most likely to identify themselves as aligned with particular method (Weis et al., 2019). Therefore, MM projects require educating team members about MM research on theoretical and practical levels, continual dialogue about the added value of combining approaches, and developing understanding and agreement about how to produce integration through the use of the MM design. It is important that members of the project are motivated to engage in the challenge and possibilities for lifelong learning and professional development (Niglas et al., 2018). Thus, although recognizing that it is not necessary or even possible for every member of the team to hold expertise in all methods employed in a specific research project, it is important to make clear the added value of the MM approach and set out the clear division of labor in terms of when and by whom the mixing should take place (May and Burke, 2010).

Additional challenge in large-scale MM research is related to funding proposals and publishing the research results. Editors of education research journals and funding agency program officers find it difficult to both advise researchers who wish to submit work that draws on multiple methods and identify reviewers with appropriate expertise to evaluate the submissions (Weis et al., 2019). On the other hand, there is evidence that editors of educational journals increasingly encourage presenting internationally based cross-disciplinary MM research that can inform and enrich our understandings of complex phenomena related to learning and teaching (Reio, 2013; Niglas, forthcoming).

To provide means for enhancing MM practices and publication editors of the Journal of Mixed Methods Research (JMMR) and other prominent MM authors have provided numerous guidelines on quality issues in MM research and MM manuscripts (e.g., Creswell, 2007; O’Cathain, 2010; Dahlber et al., 2010; Mertens, 2011; Fetter and Freshwater, 2015; Reio and Werner, 2017; Baim-Lance et al., 2020; Cheek, 2021). Recent concise overview of the development of quality criteria and frameworks can be found in the editorial for the virtual special issue of JMMR on “Quality in Mixed Methods Research” by Fabregues et al. (2021).

It is commonly emphasized that MM publications pose a great challenge to the research teams because the volume of diverse data and analytical complexities make it difficult to meet the publication norms in terms of article length and type accepted by most academic journals (Creswell et al., 2011; Baim-Lance et al., 2020; Reio and Werner, 2017). In the early insights, the challenge of integration of qualitative and quantitative components in writing up and the need for guidance and templates for reporting of MM studies was strongly emphasized (e.g., Bryman, 2007; Creswell and Tashakkori, 2007; O’Cathain et al., 2009). The burning questions of the kind - *Should QUAN and QUAL be reported as separate studies and complemented by the section or separate publication where they are integrated?* or *Should QUAL and QUAN always be integrated throughout the writing in the context of MM studies?* – were raised and different point-of-views provided.

The simple suggestion put forward is to organize the results of a MM study into three publications QUAN, QUAL and MM article (e.g., Creswell, 2015, p. 92). While commonly noticed that the structure of the MM paper depends on the design of given empirical MM study, the need for providing a rationale for using MM design and specific evidence of integration of qualitative and quantitative components is strongly emphasized (Fetter and Freshwater, 2015; Fabregues et al., 2021).

The above-mentioned simple model of publishing can be challenged from several viewpoints. The most radical reasoning is represented by the suggestion that true MM research “cannot be divided into two articles for publication”, because in doing so the most important aspect of the analysis will be lost (Sims, 2011). Quite in the same vein, Julianne Cheek has recently argued in her editorial to the journal of Qualitative Health Research that “severing a mixed methods study into several publications is antithetical to the purpose and principles of mixed method design”. She specifically points out the problem of publishing qualitative part of the study with a clause “this work is part of a larger study” leaving the audience to wonder what were the exact design details of this larger study and if this piece is actually a qualitative study in its’ own right or just a “supplementary component of a mixed-methods study”? As a solution, to meet the page limit requirements one could provide online supplements, give a reference to the more voluminous publication like monograph or doctoral dissertation where to obtain detailed information, etc.

However, we argue, that when conducting large-scale MM programs of study neither of the publishing models described above seem to work for many practical reasons. In the large-scale studies running up to 5 years (even if purely quantitative or qualitative), the volume of data and complexities of interpretation, but also the expectations of funders concerning the dissemination, often dictate publishing the results of the study in a number of separate papers and volumes in parallel with implementing the project. Thus, the MM team has to find ways for fragmented publication of the results of the large-scale study so that not only the integrity of its’ sub-parts will be convincingly presented but also the added value of the MM design becomes tangible.

Reflections on an exemplary large-scale MM study

Our MM research project called Teachers’ Professionalism and Professionalism in Changing Context (TePP) aimed to scrutinize how global policy transformations and teachers’ life histories have affected teachers’ professionalism in Estonia. Central concepts in the theoretical framework of the TePP project were professionalism, professionality (i.e., personal concept of professionalism), and

refraction, which elucidates how teachers' professionalism and national educational trajectories vitally influence the fate of educational reform and restructuring initiatives (see [de Groot et al., 2013](#); [Goodson and Lindblad, 2010](#)).

Background and relevance of the TePP project

Contradictory demands on contemporary educational systems and standardized top-down reforms often erode teachers' motivations. Therefore, stakeholders continuously need to negotiate the meaning of professionalism of teachers to understand the expectations for teachers as professionals and to implement best practices to support them. In conditions of the continuously diversifying student population external stakeholders, and parents in particular, have become ever more demanding and are increasingly positioned as consumers in relation to teachers. First and foremost, these increasing demands concern the academic achievements of the students, in which terms the parents' expectations to their children's outcomes have considerably risen ([Mikser et al., 2020a](#)).

The lack of knowledge and attention in that respect sheds some light to the reasons of the widespread failure of educational change initiatives ([Goodson et al., 2006](#); [Sahlberg, 2010](#); [Wallace, 2003](#)). Thus, the broader problem that shaped our research focus was that previous studies and the international policy discourse of change have insufficiently succeeded in explaining actual changes in teachers' professionalism and professionalism, and in education and social sphere more generally.

Additionally, we acknowledged that rather little attention has been paid to the context of fundamental education change that followed the regime change in post-socialist countries. A significant inadequacy in interpreting educational change has been a scarce attention to how global initiatives are modified, redirected and potentially transformed across different spatial and temporal contexts and across various societal levels (e.g. global, national, local and individual). We argue that when global policy initiatives are implemented and their effects discussed, non-dominant social and political contexts are particularly prone to being oversimplified and misinterpreted. This tendency, in turn, evokes avoidance and resistance against global reform initiatives in these contexts, particularly at sub-national levels ([Goodson and Mikser, 2022](#)).

The reception and implementation of global educational reform initiatives is a multilevel, reciprocal and complicated process, where initiatives from one level are rarely if ever uncritically accepted at another level. More often, these initiatives are ignored, redirected, resisted or, in some cases, rejected altogether. In this process, teachers deserve particular attention, because the success or the failure of large-scale educational reform initiatives ultimately depends on each of them ([Mikser and Goodson, 2018](#)).

Oversimplifications and misinterpretations occur on various dimensions. In the *temporal* dimension, changes are too often analyzed from an unreasonably short time perspective, whereby persistences and continuities, however influential, are unjustifiably ignored. For example, certain mentalities and practices of socialist-experienced teachers are routinely misattributed to the authoritarian influences of the Soviet period, whereas in fact these practices can result from much older traditions of certain educational schools of thought or of a country under observation. Distortions on the *spatial* dimension typically occur when cardinal points and other geographical concepts are expanded and misapplied to mark, amplify and perpetuate geopolitical discriminations. [Wolff \(1994\)](#) has thoroughly demonstrated that the East-West geopolitical axis in Europe is far from being a neutral construction, nor was it invented only during the Cold War period. From the Enlightenment, the construction of "Eastern Europe" served as Western Europe's first model of underdevelopment, which the later historical periods have accommodated and perpetuated. Derivatives such as "Eastern European" are used to mark people as well as their mentalities and modes of behavior, in order to legitimize the application of neoliberal policies in these socio-historical contexts ([Goodson and Mikser, 2022](#)). The same practices are also applied to other non-dominant contexts in global East and South ([Tabulawa, 2003](#)).

Finally, distortions on what we call the *representational* dimension occur when the interpretation of changes by representatives of one societal level (e.g. state level) disproportionately dominates over those of other societal levels. State policy representatives, local authorities, school leaders, individual teachers and other interest groups can interpret reform initiatives in different and even contrasting ways. [Goodson and Mikser \(2022, p. 12\)](#) explain:

The conflict typically appears between the systemic narrative that includes the storyline of major transitions as described in state policy documents, research and media outlets, and the personal and professional narratives which appear in the life histories of individual professionals.

The systemic narrative is not neutral, since its composers necessarily tend to select and interpret the documentary sources according to their own reform agenda. As [Kitaevich \(2014\)](#) demonstrates in the Georgian context, state narrative is heavily overrepresented at the expense of that of individual educational professionals. This representational conflict, in turn, can reveal the hidden aspirations of neoliberal policies, in which case the stigma of "(post-)socialist" is used by policy makers to subject teachers to the new, arguably liberal democratic requirements of standardization and accountability ([Silova and Brehm, 2013](#)).

The central line of MM design in the TePP project

Institutional grant awarded to our team by the Estonian Research Foundation enabled to carry out large-scale research project with duration of 5 years (2014–2019) led by principal investigator and 6 senior staff members. During the project 24 other researchers and more than 10 Ph.D. candidates were involved in specific research activities for shorter periods. Active dissemination of the results was expected by the funders throughout the project. In the final report ca 45 publications were listed, 5 defended Ph.D.

dissertations and more than 10 defended master theses were related to the project. Additionally, several publications have been published and doctoral dissertations defended after the official end of the project. Although the core team was formed from the members of the same faculty, the co-operation with international partners enriched the project and provided opportunities to gain new insights.

The aims and research questions of this large-scale study were complex and multifaceted demanding integration of macro-level processes with personal micro-level conceptualizations and practices of teachers. Therefore, our early decision was to integrate systematic policy analysis, large-scale quantitative survey, and in-depth qualitative interviews with teachers, academic professionals and education policy makers from various historical contexts (who, in our terms, covered different levels at the representational dimension). Sequential MM design was chosen for integrating qualitative and quantitative methods, so that methodological decisions during later stages of the study could be informed by the results from the earlier stages, but also to allow the results of the earlier stages to be explained and enriched by the analysis in the later stages. Referring to the widely used typology by Jennifer Greene (2007) the main purposes for mixing were development and complementarity (i.e. seeking elaboration, illustration, enhancement, and clarification of the findings from one analytical strand with results from the other analytical strand).

Three educational sectors – general education, early childhood education, and vocational education – were represented by the leading members of the team. Some of us had stronger backgrounds and experience in qualitative research and others in quantitative research, but everybody welcomed the MM approach and suggested to share the workload not by the quantitative and qualitative stages of the study, but to divide the team into three workgroups according to educational sectors mentioned above. This resulted in a two-level shared leadership model where the role of the principal investigator was seen most importantly as the conceptual leader and coordinator of the team (Niglas et al., 2018). All workgroups implemented the same general MMR design, but it was agreed that some details like the sampling principles and data collection instruments might vary according to the contextual needs of the particular educational sector.

The TePP study was divided into four stages (see Fig. 1). It started with document analysis and secondary analysis of existing empirical evidence with the aim of mapping the historical background and changes in theoretical, ideological, and normative

Integration for complementarity	Stage of the study and main output (=>)	Integration for development
	Stage 1: Historical and background analysis	
	1.1 policy analysis	
	1.2 newspaper analysis

concepts of teachers' professionalism. To complement policy analysis, number of expert-interviews were carried out with experienced teachers and educational administrators (see, for example Mikser and Goodson, 2018; Loogma et al., 2019; Loogma, 2016).

On the next stage, we implemented large-scale survey with representative samples of 653 preschool teachers, 897 general education teachers and 501 vocational education teachers to test models of professionalism to identify possible typologies of teachers by understanding their perceptions of professionalism and identifying the factors they attributed to the changes of professionalism. We also intended to shed some light on the implications that different concepts of professionalism might have on teachers' work and teaching practices (see, for example Sirk et al., 2017, 2020; Mikser et al., 2018; Näkk and Timoštšuk, 2021).

The third stage of the project involved two-step narrative life history interviews with purposeful samples of 15 preschool teachers, 63 general education teachers and 24 vocational education teachers. The main aim on this stage was to provide detailed understanding about the paths that teachers have followed to develop certain views on professionalism and about the perceived changes and influences forming teachers' professionalism (see, for example Goodson and Ümarik, 2019; Ümarik and Goodson, 2020; Mikser and Goodson 2020; Näkk and Timoštšuk, 2021).

In the final stage, which has continued after the formal end of the project, we have closely interrogated the juxtapositions between teacher professionalism and teachers' professionalism. The meta-analysis integrating the main results of the MM program was theoretically framed. For example, social ecology approach was applied for interpreting the results from vocational education (Loogma, 2020), while the results indicating shift toward and tensions about learner-oriented teaching in general education were conceptualized following motivational theories (Timoštšuk, 2020). Initially, the scenarios for future development of teachers' professionalism were planned to be constructed, to explain and clarify possible policies and choices for actions. However, due to the limited empirical data with the focus on the future trends, the scenarios were not provided as the main outcome of the project.

In the light of the above it can be recognized that from the methodological perspective, our aspirations were ambitious, yet we believe that learning from the experiences of our exemplary large-scale MM study is potentially useful for further investigations on the patterns of implementation of educational reform initiatives in different contexts.

Added value and challenges of MM design – some examples with discussion

The first stage of the TePP project incorporating analysis of several data sources (see Fig. 1) produced vast pool of results which were integrated on the later stages both for instrument development and complementary interpretation of empirical outcomes, but also for enhancing the theoretical conceptualization of the *refraction*, that was central notion in our project.

Development of the survey instrument and the choice of indicators was informed and validated by the results of the documentary and secondary analysis carried out during the first stage of the project. Quite traditionally, the secondary analysis of existing quantitative and qualitative studies helped to reduce the amount of new data we needed to collect by the survey instrument. On the other hand *systemic narratives*, constructed on the basis of content analysis of policy documents (incl. relevant newspaper articles) and data from expert interviews (Loogma, 2016; Loogma et al., 2019; Tinn, 2020), helped to compose the periodic list of the reforms and related (policy) changes, which were used as a backbone in the survey instrument.

The general education workgroup defined *professional learning* as an important additional focus, conceptualizing it as a constant journey of becoming a better teacher. Using social learning theory (Wenger, 1998, 2010) as a methodological framework, the semi-structured interviews with teachers' about their learning experiences focusing on their professional practice, meaningful experiences, teachers' identity, and belonging were carried out. The contradiction between teachers' liberal values (such as appreciation of the learner's individuality and humanity) and educational performance and measurement orientation was found (Timoštšuk et al., 2018). This triggered the workgroup to add an extra section into the survey instrument exploring the relationship between teacher work motivation and their teaching practices.

The importance of the input from the first stage of the study into development of the survey instrument as well as providing historical and political context for interpreting the survey results has been emphasized by the senior staff members, however, we reflect that this MM aspect was not very clearly displayed in publications where the survey results were presented (see Mikser and Goodson, 2018; Sirk et al., 2017, 2019, 2020; Timoštšuk et al., 2018). Recognizing the varying challenges (like traditional forms of publishing in quantitative-biased journals or time-pressure in preparing the publications within the large-scale MM project) hindering the just presentation of the input from the prior qualitative phase of the study, we encourage finding ways for clearly demonstrating the added value by incorporating the MM aspect even if it has had only facilitating role at given point.

The survey results, enriched by the input from the first stage of the research project, enabled reliable and generalizable comparisons of the factors that teachers attributed to their professionalism in different education sectors in Estonia. For example, the collaboration was indicated as the key factor, determining the professionalism of vocational education teachers (Sirk et al., 2017). At the macro/institutional level, the problem of low status of VET has historical roots, strengthen by the signals from labor market (Loogma et al., 2019). This macro factor has consequences of the characteristics of the VET students and therefore, to VET teachers professionalism (Sirk et al., 2016). The relation between policy changes and VET teachers' professionalism are not unambiguous. Results concerning the VET teachers' professionalism demonstrated the differentiation of VET teachers' community on the basis of their scope of collaboration and as well, identify the collaboration as determining factor of professionalism (Sirk et al., 2017). The differentiation of teachers manifests also in teachers' attitudes toward reform changes.

The results of historical and policy analysis and conceptual apparatus built during the first stage of the project gave also important input for analyzing spatial and temporal refraction in the survey results of preschool and general school teachers. The results from preschool teachers' survey indicated an apparent inconsistency in teachers' views on changes in pre-service preparation

curricula concerning then balance between theoretical and practical parts of the study. This echoed our earlier results, and enforced our understanding of neoliberal policies as keeping different stakeholders (e.g. practitioners and policy makers) apart from each other, which results in “policy evasion” by practitioners (Mikser and Goodson, 2018; Mikser et al., 2019).

As the main output of the survey study, the typology of teachers, based on differences in perceptions on professionalism, helped to determine the implications that different concepts of professionalism have on teachers’ work and teaching practices, as well as to explore the on-going relationship between concepts of professionalism and professionalism. For instance, different clusters of Estonian preschool teachers had considerably different views and expectations of educational reforms as reflected by the survey results. However, all clusters alike tended to place low value on further academization of preschool teaching profession, both in terms of the university-based training and participation in the research activity (Mikser et al., 2019).

On the other hand, the general education workgroup found that teachers’ self-reported perceptions on autonomy support and structured teaching did not vary significantly. Overall, teachers prioritized autonomy support and intrinsic motivation in learning (Timošćuk and Näkk, 2020). This seemed to be to some extent in contradiction with adjacent results and therefore additional data collection through classroom observations and students’ self-reports was introduced for validation purposes. The results revealed that teachers’ self-reports about their autonomy-supportive and structured teaching practices followed their actual teaching. Nevertheless, the context of teaching (room settings, students background and experiences) significantly influenced students’ learning engagement (Näkk and Timošćuk, 2019). This example illustrates the added value that allowing openness in conducting MM projects may bring about. The core design of our MM study was enhanced by emergent design elements (Schoonenboom and Johnsson, 2017) bringing in another purpose for mixing quantitative and qualitative approaches – namely triangulation (Greene, 2007).

For the third stage of the project, it was planned that teachers from different educational sectors and age cohorts would be selected for narrative *life history interviews* based on the typology of teachers constructed as a result of the survey study. This plan was implemented by the vocational education workgroup (Ümarik and Goodson, 2020; Goodson and Ümarik, 2019; Loogma, 2018), while for the other workgroups the plan was altered due to the practical reasons like the need to start collecting the interviews earlier than the analysis of the quantitative data was finished, being not able to identify and connect with the selected participants as most of them preferred to answer the survey anonymously, etc. However, the careful purposeful selection of the participants for the life history interviews based on the age cohorts and other contextual factors like subject taught, educational background, ensured that the opinions of different generations were represented and longer-term cultural trajectories present within each context. This enabled to draw indirect connections and comparisons with emerged clusters of teachers allowing to bring in some integrated interpretations (e.g., Mikser et al., 2020; Näkk and Timošćuk, 2019).

In the life history interview method, it is essential that in the first interview the open unstructured style is practiced, which allows the person to tell the life story that she wants to tell. All life history work, by definition, has to be the life story as experienced and represented by the storyteller. The subsequent interviews with the same respondents are more reciprocal and structured, allowing the interviewer to cross-question the major points of interest, the contradictory items and the unfinished utterances (Mikser and Goodson, 2018). In our TePP project life history interview questions for the second round were developed on the basis of all previous stages — documentary analysis, survey results, and preliminary results of the first round of interviews that asked for interviewees’ personal interpretations of their life-course and work.

While the survey results were integrated on the third stage of the study serving the development purposes, the results from the life history interviews were used to help to understand more deeply the refractions from the systemic narratives and other tendencies that the survey illuminated. The survey with preschool teachers revealed controversies in the respondents’ views on changes in teachers’ professionalism. On the one hand, the global tendency of raising preschool teachers’ formal qualification requirements was generally appreciated as a symbolic credential of their status as teachers (Mikser et al., 2020). This appreciation, however, was intertwined with preschool teachers’ widespread alienation from “theoretical” studies, possibly because this is traditionally not associated with their professional identity and, secondly, because theory is perceived as being presented in political and ideological terms and detached from teachers’ daily practice (Mikser et al., 2018). Moreover, although remarkably different attitudes toward professionalism existed *within* preschool teachers as a professional group, nearly all the respondents alike tended to be averse toward academic career (including Ph.D. education) and research activity. The global trend of raising the requirements for preschool teachers’ professional preparation is thus refracted in the Estonian preschool teachers’ mindsets that on the one hand rely upon the Nordic, homelike and non-academic tradition of preschool and on the other hand on the Soviet model, where teachers’ work was tightly regulated and requirements for professional preparation were therefore low. Our life history interviews with preschool teachers confirmed that although teachers generally perceived their work as having become more difficult over the course of their professional career, the rising qualification requirements and the widespread curriculum autonomy officially assigned to teachers has a valuable and alleviating psychological impact on them (Mikser et al., 2020).

The life history interviews with teachers from schools of secondary education revealed historical and cultural refractions from the systemic narrative in a different manner. Whereas preschool teachers’ concerns were largely related to achieving the political and public status as teachers (and not caretakers), the school teachers’ narratives expressed hesitation and incredulity toward the policy rhetoric which on the one hand grants them with professional freedom and autonomy, but on the other hand subjects them increasingly to external accountability and output control (Mikser and Goodson, 2018, 2020; Tinn and Ümarik, 2021).

The analysis of teachers’ life history interviews on the third stage of the project yielded a *re-periodization* of the systemic narrative, which we consider significant added value from MM approach. Instead of the overwhelming progress rhetoric that is apparent in the systemic narrative of the transition period (i.e. “things always become better”), many experienced teachers perceived the 1990s as “a window of opportunity” between the oppressive circumstances of the Soviet system on the one hand and the current neoliberal

education policies on the other hand (Mikser and Goodson, 2020). Furthermore, although the experiences from the Soviet period are often described as espousing outdated mentalities and practices and lacking individual initiative, creativity, responsibility and tolerance, the experienced teachers' narratives demonstrated insightful and nuanced understandings of the difficulties in balancing between the oppressive external circumstances and their own values, beliefs and practices. Contrary to the narrative, widely spread in parallel with recent reforms, professionalism in the Soviet circumstances required independence, creativity, responsibility and a highly critical mindset (Mikser and Goodson, 2020).

Thus, the juxtaposition of the (state-enhanced) *systemic narrative* (developed on the first stage of the project), survey results and teachers' *work life narratives* provided basis for truly integrated insights into the impact of neoliberal educational reforms on teachers' life and work in Estonia (Tinn, 2020). The interview results contributed to explaining the results of the quantitative survey study and added new dimensions to the historical grid by showing how teachers' personal life paths had shaped their perceptions of educational changes and societal demands on their professionalism. Most importantly, these results indicated that some negative consequences of the reforms as perceived by teachers, were the effect of refraction rather than directly caused by the initial aims of the reforms (Mikser and Goodson, 2020). Drawing parallels with earlier studies we hope that our results provide valuable contribution for explaining refractions in educational reforms also in the other former socialist European countries.

As mentioned earlier, to explain and clarify possible policies and choices for action, the scenarios for future development of teachers' professionalism were planned to be constructed as the final stage of the TePP project. However, we realized that the rich empirical data we had collected was mostly reflecting on the past events and experiences. The latter in interplay with the practicalities of the large-scale MM study and complexities of the integrated analysis, putting considerable time-pressure on the team, led to the decision to renounce the development of the scenarios. However, the vocational education workgroup tackled the challenge of constructing some provisional scenarios (see Loogma et al., 2020) building on the selected results from the first stage of the project giving some input for identifying trends of the development of teachers' professionalism in the future.

The intrinsic interest toward further conceptual development of the notion of refraction and related methodology has motivated the team to continue their joint research and publication activities after the formal end of the TePP project (e.g., Mikser et al., 2020). For example, Mikser et al. (2020) have further elaborated and combined the data from survey and life history interviews from Estonian preschool teachers. In this chapter they analyze and discuss *symbolic capital* as applied to the professionalization of Estonian preschool teachers, building on conceptual elaboration of teacher professionalism as *symbolic capital* based on the previous work of Bourdieu, Schinkel and Noordegraaf (e.g., Schinkel and Noordegraaf, 2011).

Concluding remarks

Being inspired by earlier findings of Goodson and his colleagues (Goodson, 2010; Goodson and Rudd, 2016), pointing out that different historical periods and country- or region-specific trajectories generated significant refractions from global, homogenizing neoliberal educational reform initiatives, the large-scale MM research project TePP was initiated in Tallinn University with the focus on the educational reforms the Estonian teachers had experienced over several decades including transition from socialist period. The results from our project detected refractions from the conventional perceptions of the mentalities of socialist-experienced teachers. This finding supports the

argument that the global initiatives are not straightforwardly adopted in various contexts. Instead, they are "modified, redirected and potentially transformed, providing spatial, temporal and representational variations" Goodson and Mikser (2022, p. 2). As, on the other hand, the global initiatives can not and are not completely ignored or rejected the findings from the TePP study are relevant in the other educational contexts, and especially in the context of former socialist European countries.

We consider that MM research design, that we purposefully implemented played an important role on multiple levels. It helped us to get deeper and multifaceted understanding of teachers' perceptions on their professionalism and its' interplay with educational reforms initiated in the context of global policy transformations. We have noticed that in studies on curriculum policy official documents and systemic guidelines are often considered as the natural starting point against which a certain curricular aspect is to be measured. The latter approach has serious limitations in terms of understanding the reality of schooling or illuminating mechanisms by which existing patterns of power and governance are transformed and maintained:

Politically conservative and quietist, such research leaves both the managerial class and teachers playing on their own grounds, so leaving politicians and managers space to develop and to impose narratives on a population which is experiencing something very different from what the narrative is telling them.

Mikser and Goodson (2020).

Our research strategy allowed to juxtapose top-down systemic narratives covering different educational levels with teachers' work-life narratives and their attitudes toward educational changes and is therefore "emancipating in the sense of demonstrating how myths are made by governments right through the major changes in political systems and are then peddled as systemic narratives" (Mikser and Goodson, 2020). Being able to reveal such aspects attributes certain political importance to the MM research design implemented in our project.

The meta-analysis presented in the first part of the chapter and our experiences from an exemplary large-scale MM study demonstrate that while the approach is potentially very fruitful the research team has to meet number of challenges to fully exploit and raise all the prospects of this promising methodological approach. Therefore, when planning a large-scale MM study, it is important to pay duly attention to the challenges highlighted in this concise chapter and to take special care that time for screening possible other obstacles would be allocated early in the project so that the teamwork and methodological expertise of the team could be adequately facilitated.

It is not surprising that in parallel with challenges in managing the team dynamics, the integration of the findings from different stages of the project needs special attention. However, our experiences indicate that the publication appears to be even more serious stumbling block. Our self-critical glance to the publication practices within TePP project indicate that the divergent presentation of the sub-parts of the study and findings does not effectively convey the general methodological framework and added value of the implemented MM strategy of the large-scale project even if the integrated results are interwoven into the discussion.

Anecdotal evidence can be pointed out where the modest attempts from the team to propose an MM article presenting the results of some parts of the large-scale study was rejected by the editors and substituted by the authors with the paper presenting only a certain quantitative or qualitative stage of the larger MM project. At the same time, we recognize that the number of editors calling for MM papers and chapters is increasing and ultimately the worth of MM publications depends on the quality of MM inquiry that is presented and the proficiency of the MM team to link the publications so that the role of any separately published part will be adequately understood and interpreted within the larger MM framework. To conclude we argue that specific issues concerning publishing in the framework of large-scale MM programs of study are not thoroughly discussed and need further examination.

Glossary

Conceptual framework A collection of concepts and empirical findings from the literature, used to show relationships among ideas and how they relate to research.

Descriptive research The second level of the knowledge-level continuum that uncovers descriptive information on the topic of interest using qualitative and/or quantitative methods.

Existing data Data already collected by you or someone else that can be used in a new research project. Also referred to as “secondary data.”

Existing qualitative data Text, visual, or recorded (e.g., audio, video) data collected by you or someone else that can be used to address a new research question.

Existing quantitative data Numerical data collected by you or someone else that can be used to address a new research question.

Explanatory research The highest level of the knowledge-level continuum and is conducted using quantitative methods of inquiry because previous data exists on the topic of interest.

Exploratory research The first level of the knowledge-level continuum; includes research that begins to fill the substantial gap in the existing literature related to your topic of interest.

Knowledge-level continuum A framework for describing the progression in the levels of scientific inquiry. If there is little to no pre-existing knowledge on your topic of interest, an exploratory level of investigation should be used. If some pre-existing knowledge exists, a descriptive level should be used. If there is a robust amount of pre-existing knowledge, an explanatory level should be used.

Mixed methods The rigorous and epistemological application and integration of qualitative and quantitative research approaches to draw interpretations based on the combined strengths of both approaches to influence research, practice, and policy.

Mixed methods with existing data Identifying, evaluating, and incorporating one or more existing (i.e., secondary) qualitative or quantitative data sources in a project.

Primary data Data collected in real-time to achieve the goals outlined in a research project, also called “original” or “raw” data.

Secondary data Data already collected by you or someone else that can be used in a new research project. Also referred to as “existing data.”

Theory An explanation of the “how” or “why” of phenomena, typically referencing existing facts. A theory is usually based on an existing framework and is frequently tested.

Introduction

Funders and publishers are instrumental in establishing the guidelines and processes we use for sharing data (Chawinga and Zinn, 2020). Education researchers—particularly those who use existing data (or “secondary” data) sources in mixed methods—can benefit from the recent increase in accessible data, as the advantages of using existing data in education research are far and wide (Logan, 2020; Smith, 2011). One of the most fundamental benefits of existing data is its ability to extend the knowledge about a research topic above and beyond the current state of the science. For example, a growing body of literature and data sources considers the impact of the global COVID-19 pandemic on students’ learning and educational experiences (Dorn et al., 2020; Grooms and Childs, 2021). Existing data sources that include COVID-19-related items or information about student experiences during the global pandemic can be used to extend the field’s understanding of educational disparities and shifting academic norms. Existing data provide an opportunity to think critically about a research question outside its initial parameters, using data collected by you or someone else. Furthermore, having a chance to work with existing data gives researchers an insider view of a complete dataset, its strengths and weaknesses, and its ability to address a research question associated with their research interests. An insider view of a project can also teach budding researchers how to lead their own research projects.

This chapter describes how researchers can use existing data in mixed methods projects to advance education research. We begin by defining existing data for mixed methods using an education research context. We then cover the advantages and disadvantages of using existing data broadly and in mixed methods projects. Next, we present the knowledge-level continuum as a way to frame the exploratory, descriptive, and explanatory research conducted in educational settings. Then, we use examples from education research to describe existing qualitative and quantitative data in mixed methods and how to “mix” these data to answer research questions. Easy-to-follow instructions do not always accompany existing data sets. Therefore, sifting through data records and making sense of the available information associated with existing data sets is an essential part of the process. We end with a discussion of how existing data can support the deepening of knowledge and the breadth of educational topics researchers and practitioners can explore.

What are existing data in mixed methods?

Mixed methods are the rigorous and epistemological application and integration of qualitative and quantitative research approaches to draw interpretations based on the combined strengths of both approaches to influence research, practice, and policy (Plano Clark and Ivankova, 2016; Creswell, 2015; Watkins and Gioia, 2015). John Creswell (2015) defines mixed methods as:

An approach to research in the social, behavioral, and health sciences in which the investigator gathers both quantitative (closed-ended) and qualitative (open-ended) data, integrates the two, and then draws interpretations based on the combined strengths of both sets of data to understand research problems (p. 2).

Previous definitions of mixed methods clearly distinguish between quantitative and qualitative data. However, they rarely note whether these data can come from existing data sources or are newly collected data specific to each mixed methods project (Watkins, 2022). Given the importance of this distinction, we insist that one might use at least two types of data in their mixed methods: primary and secondary data. *Primary data* are collected in real-time to achieve the goals outlined in a research project. Other names for primary data are “original” or “raw” data. *Secondary data*, or “existing” data, are the data that have already been collected by you or someone else that can be used in a research project. Various data sources exist, ranging from large, publicly available data (e.g., US Census data) to smaller, privately-owned data (e.g., local social service agency data of the client population). Whether they include publicly available case studies, data points, papers, artifacts, or electronic documents, existing data are valuable in education research (Logan, 2020). Scholars have gone to great lengths to define mixed methods studies apart from qualitative and quantitative single-method studies (Bazeley, 2018; Creswell and Plano Clark, 2018; Hesse-Biber, 2010; Mertens, 2009, 2017; Morse, 2009). Mixed methods have also been described across various disciplines (Curry and Nunez-Smith, 2015; Johnson and Christense, 2013; O’Cathain, 2010) and professions (Andrew and Halcomb, 2009; Haight and Bidwell, 2016; Johnston, 2012; Magee et al., 2006; Sheperis et al., 2016; Watkins and Gioia, 2015). Yet, sparse resources provide clear guidelines for what mixed methods with existing data involve.

Existing data can be either qualitative or quantitative. Smith’s (2008) book *Using Existing Data in Education and Social Research* provides a concise account for using existing qualitative data in social science research. The author affirms that existing data “... can be numeric or non-numeric. Non-numeric, or qualitative secondary data can include data retrieved second hand from interviews, ethnographic accounts, documents, photographs, or conversations” (pp. 4–5). Though most existing data sources tend to be quantitatively oriented, Smith reminds us of the possibilities of existing qualitative data in our education and social research endeavors. Let’s consider an example pertinent to education research. Charlie is a graduate student interested in examining K-12 students’ sense of belonging within the virtual learning environment since the COVID-19 pandemic. Currently, the knowledge base on virtual learning since the start of the pandemic is still relatively new, so there is little to no data on students’ sense of belonging in the widespread but new virtual learning environment. Charlie’s first step is to finalize the research question, then search for existing

data sources to address the research question. What if Charlie helped collect data on a similar topic for their professor when COVID first began? Does this still count as “existing data?”

Adding a time element to the definitions of primary and existing data is critical when distinguishing between the two because you can collect primary data now that you use for secondary purposes later (Watkins, 2022). There is no hard and fast rule to the length of time that must pass before primary data can be considered “existing” data. The only real distinction involves whether someone has a fundamental research question they want to answer and whether the data to address that question exists. For example, if Charlie collected data 2 years ago and those data can help answer a different research question now, Charlie can use those data to answer the new, different research question. Whether the new research question is related or unrelated to the original study, Charlie can use those existing data for a secondary purpose.

Education research can benefit from combining mixed methods with existing data methods (Fig. 1). Mixed methods involve collecting and analyzing both quantitative and qualitative data to address a research question. Whereas existing data methods involve evaluating quantitative and qualitative data that have been previously collected and deciding how to use them for a secondary purpose. Bringing the two methods together results in mixed methods with existing data. Hence, doing *mixed methods research with existing data* involves identifying, evaluating, and incorporating one or more existing data sources into a mixed methods project (Watkins, 2022). Incorporating existing data into mixed methods takes the definition of mixed methods to a new level, as mixed methods are ways to collect, analyze, and integrate qualitative and quantitative data in rigorous and theoretically sound ways to encompass the breadth and depth of a topic (Creswell, 2015; Guetterman et al., 2015; Tashakkori and Teddlie, 2010).

Using existing data in mixed methods also expands the purpose of secondary data analysis, which is to further analyze an existing data source by addressing a research question like (or distinct from) that for which the original data were collected (Hewson, 2006). Increasing our use of existing data sources adds to the unique possibilities for the future of mixed methods in education research. Previous studies suggest existing data are typically used at the beginning (or for the first phase) of a mixed methods study (Hewson, 2006; Johnston, 2014). However, as qualitative and quantitative data sources become more robust and sophisticated, the potential for implementing entire mixed methods studies using education data previously collected for a different purpose is promising.

Using data collected by you or someone else to answer your research questions is common in education research and academic settings (Davis-Kean and Jager, 2017; Hewson, 2006; Panchenko and Samoilova, 2020). It can maximize a project’s resources (e.g., time, resources, and energy) beyond those used for its original purpose. The purpose statement, research questions, and theory should guide the decision to use existing data in a mixed methods project. Further, applying or generating theory in mixed methods with existing data will vary depending on whether the research prioritizes the quantitative or qualitative phase of the study. For instance, let’s revisit the education research example presented above. Suppose Charlie wants to investigate students’ sense of belonging within the virtual learning space, and there is little pre-existing knowledge about students’ sense of belonging specific to virtual learning. In that case, Charlie must prioritize a research approach that allows them to gather more comprehensive insight into how students describe their connectedness and belonging to peers and educators within the virtual space. Charlie might use mixed methods with existing data for this study. Moreover, Charlie should also review the advantages and disadvantages of using mixed methods with existing data before proceeding.

Advantages and disadvantages of using existing data in mixed methods

There are several advantages to using existing data in mixed methods. For example, using existing data to address a mixed methods question may save time, money, and the resources necessary to collect primary data. Also, researchers might decide to use existing data because they have access to a high-quality and robust data source. Students are drawn to existing data for their mixed methods because the data can extend their current scholarship. Deep diving into someone else’s data can expand a researcher’s training and scope. Though one’s education, training, and skills are unique to them and allow them to view the world through a particular lens, this uniqueness might also limit the researcher’s contribution to research. In short, using existing data can enhance a researcher’s scope and abilities.

Fig. 1 The merging of methods: mixed methods with existing data.

Despite the advantages of using existing data in mixed methods, there are also some challenges. For example, some researchers might find using someone else's data mysterious and unclear. Budding researchers may also question their authenticity because they did not undergo all the steps in the research process (e.g., idea conceptualization, IRB application, recruitment, instrument development, data collection, data analysis, reporting, etc.) to achieve their project goals. Then there is the matter of missing information. Sometimes existing data files are incomplete, leaving researchers who want to use the data for secondary purposes confused about the procedures undertaken by the original research team and uncertain about the best way to repurpose the data to answer a new research question. Despite the challenges associated with existing data, they can be valuable for education research and can help streamline the path to answering the research questions. However, it is best to start at the beginning of scientific inquiry to address a research topic to do this well. This process involves deepening your understanding of your topic and the ways mixed methods with existing data can enhance exploration in an educational context. To do this, researchers must examine the topic, and the possibility of using existing data for a mixed methods study in the context of the knowledge-level continuum.

Existing quantitative data in mixed methods

Though the popularity of existing qualitative data has increased (Beck, 2019; Hughes and Tarrant, 2020; Largan and Morris, 2019), historically, education researchers who have used existing data in their studies have been guided by the quantitative data. In other words, the quantitative data are the dominant or prioritized phase in the mixed methods. Theory will guide the variables used if the researcher prioritizes the quantitative study component in mixed methods research. In sequential designs, prioritized phases occur before other phases of the study. Suppose the prioritized quantitative step involves using an existing dataset. In that case, the theory used by the original investigators will guide your understanding and selection of the pre-existing variables in those data to help answer your research questions.

Existing quantitative data can come in many forms, from thousands of individual high school student cases to a dozen or so school administrative cases in your office building. Existing quantitative data are everywhere and include population-based studies, which use methods to survey all people within a specific population (e.g., US census). Other examples of existing quantitative data are cohort-based and longitudinal surveys, such as the National Survey of American Life, conducted from 2001 to 2003 (Jackson et al., 2004). Though previously collected sources exist, researchers still need to request access to the data or investigate if the data are publicly available. A Google search of "data repository" would help you start your journey to identify publicly available existing quantitative data.

Gauge the quantitative "breadth" of a topic, then proceed qualitatively

Existing quantitative data in a mixed methods study can help you gauge the breadth of a topic before you proceed with the qualitative inquiry. Quantitative inquiry uses deductive reasoning to test and confirm (or refute) a theory (Grinnell and Unrau, 2018). This process usually begins with a theory and then establishes a plan to confirm or refute that theory. Given the sheer number of cases that can be observed using quantitative methods, there are apparent advantages to analyzing existing quantitative data. One clear advantage is gauging the quantitative breadth of a topic before deciding how to proceed qualitatively. For example, let's assume you are a data analyst at Booker T. Washington High School. Your assistant principal has asked you to explore possibilities with the school's confidential student survey data. You decide to use these existing quantitative data to understand what adolescents think about the social-emotional learning services offered by Booker T. Washington High School. After you get descriptive data about students' feelings about social-emotional services, this information could be strengthened by a small, qualitative study in which you assemble groups of students who represent the demographics reflected in your existing quantitative analysis and then ask them to expound on your quantitative findings with new qualitative responses.

Existing qualitative data in mixed methods

In qualitative research, inductive reasoning identifies patterns that generate theory. Compared to mixed methods with a dominant quantitative component, theory plays a different role with a dominant qualitative component. Rather than guide the selection of variables to test the theory, when using existing data in mixed methods, the data generate theory, or in most cases, a conceptual framework that can be tested with quantitative data. In this context, a *theory* explains the "how" or "why" of phenomena, typically referencing existing facts (Kimmons, 2022). A theory is usually based on an existing framework and is frequently tested. On the other hand, a *conceptual framework* is a collection of concepts and empirical findings from the literature used to show relationships among ideas and how they relate to research. For the purposes of this chapter, conceptual frameworks are "preliminary theories" you hope to evolve into testable explanations for the how and why of a particular phenomenon. When beginning mixed methods with a dominant qualitative component, you might consider building a preliminary conceptual framework (to test as a theory in a subsequent study). Whether you plan to generate theory (e.g., qualitative analysis) or test theory (e.g., quantitative analysis), the theory has a role in mixed methods that should be embedded throughout your research.

Existing qualitative data (e.g., text, image, etc.) provide insight and help address some of your unanswered qualitative research questions. Though not as popular as their quantitative counterpart, existing qualitative data has gained some traction from previous scholars (Bishop, 2007, 2009; Fielding and Fielding, 2000; Hammersley, 2009; Hinds et al., 1997). In particular, and given the increased respect, rigor, and credibility of qualitative data in recent years, more scholars consider its use in an existing analysis

capacity. In fact, in 2019 and 2020 alone, three books were published on secondary analysis of qualitative data (Beck, 2019; Hughes and Tarrant, 2020; Largan and Morris, 2019). Despite this progress, a comprehensive appreciation for existing qualitative data lags that of existing quantitative data. This seems to be due to the plethora of resources and guidelines for using existing quantitative data compared to the sparse resources available for using existing qualitative data. Some examples of existing qualitative data may include video recordings, audio recordings, and text documents (i.e., transcripts) of previous interviews with students.

Gauge the qualitative “depth” of a topic, then proceed quantitatively

Qualitative research uses inductive reasoning, beginning with observations and ending with theory. Therefore, if information from an existing qualitative data source aligns with the information needed to address your research question, you should consider using these existing qualitative data as a source for your mixed methods. There is an implied depth associated with qualitative research; therefore, you can immerse yourself in the data, conduct a rigorous qualitative analysis, then generate a conceptual framework (i.e., preliminary theory) that connects relevant concepts about your topic of interest. Deep inquiry into existing qualitative data can serve as a springboard for building a new quantitative study component into your mixed methods project.

Let’s consider another example where your mentor owns a qualitative data source on educational outcomes of court-appointed youth, and you are interested in exploring these data further. You and your mentor study this topic, but he collected focus group data three years ago and recently received a Department of Education grant to which he needs to turn his attention for the next 5 years. He offers the data to you to help advance your scholarship in this area. Using your mentor’s existing qualitative data can help you gauge the depth of the educational outcomes of court-appointed youth so that you can know how you want to proceed quantitatively. Namely, you could analyze the focus group data to generate a list of concepts and themes for which a conceptual framework can be created. After which, you could collect new quantitative data (including items that measure the concepts and themes generated from your qualitative analysis) to generate hypotheses and test your conceptual framework. These ideas are ways to enhance the use of your mentor’s existing qualitative data by repurposing them so that you have some direction in your research.

Both quantitative and qualitative data have advantages and disadvantages, but sometimes researchers are reluctant to use qualitative data as an existing data source. This is unfortunate given the plethora of possibilities for open-ended inquiries into the human experience. For example, there are benefits to assessing social and cultural contexts, connections, relationships, and subjective processes that result from social phenomena (Watkins and Gioia, 2015). Furthermore, uncovering the factors that influence decision-making and the opinions of research participants will strengthen your research, not weaken it.

The knowledge-level continuum in mixed methods

To understand how mixed methods with existing data can be helpful in education research, start by making decisions about your study based on the current research. This framing of education research can help because it addresses two fundamental questions when using existing data: (1) What is the existing *knowledge* on the topic? (2) What are the existing *data* on the topic? But before we ask these questions, we should first ask, what is the knowledge-level continuum and how is it helpful in guiding mixed methods with existing data in education research?

The *knowledge-level continuum* is a framework (Fig. 2) for describing the current state of science in an area of inquiry and the progression of science therein (Watkins, 2022). It outlines existing knowledge, and the ways existing knowledge merges with the organization, creation, and dissemination of new knowledge (Watkins, 2022). Previously, the knowledge-level continuum has been used in other disciplines, such as information technology (Vassallo, 1999) and social work (Grinnell and Unrau, 2018; Watkins and Gioia, 2015). Research inquiry can fall anywhere along the continuum depending on how much is already known about the topic. The knowledge-level continuum encourages researchers to think about research as being a direct by-product of the information about a topic and the purpose of the study (Grinnell and Unrau, 2018; Watkins, 2022). In short, if there is little to no pre-existing knowledge of your topic of study, an exploratory level of inquiry should be used. If some pre-existing knowledge exists, a descriptive level of investigation should be used. If there is a robust amount of pre-existing knowledge, an explanatory level of inquiry should be used (Watkins, 2022).

Let’s revisit the previous example with Charlie to understand how the knowledge-level continuum can be applied to education research. Charlie is interested in examining students’ sense of belonging in virtual learning spaces. Specifically, Charlie is interested in reviewing the factors that support and limit students’ sense of belonging in the new virtual learning environment. Let’s say Charlie completes a thorough literature search, looking through dozens of peer-reviewed article databases. Unfortunately, very little published research examines students’ sense of belonging within virtual learning spaces for K-12 students.

Additionally, of the very little information published on the topic, Charlie found it to be of poor quality, leading to challenges regarding Charlie’s trust in the rigor and quality of the research. Given the limited amount of pre-existing research and the poor quality of the research, if Charlie were initiating a research project in this area, they would use an exploratory level of inquiry. *Exploratory research* is the first level of the knowledge-level continuum. It includes research that begins to fill the substantial gap in the existing literature related to the topic of interest. Exploratory research can be conducted using qualitative methods of inquiry. For the example described, Charlie may begin with interviewing all students at a specific school who participated in virtual learning and then asking about their sense of belonging.

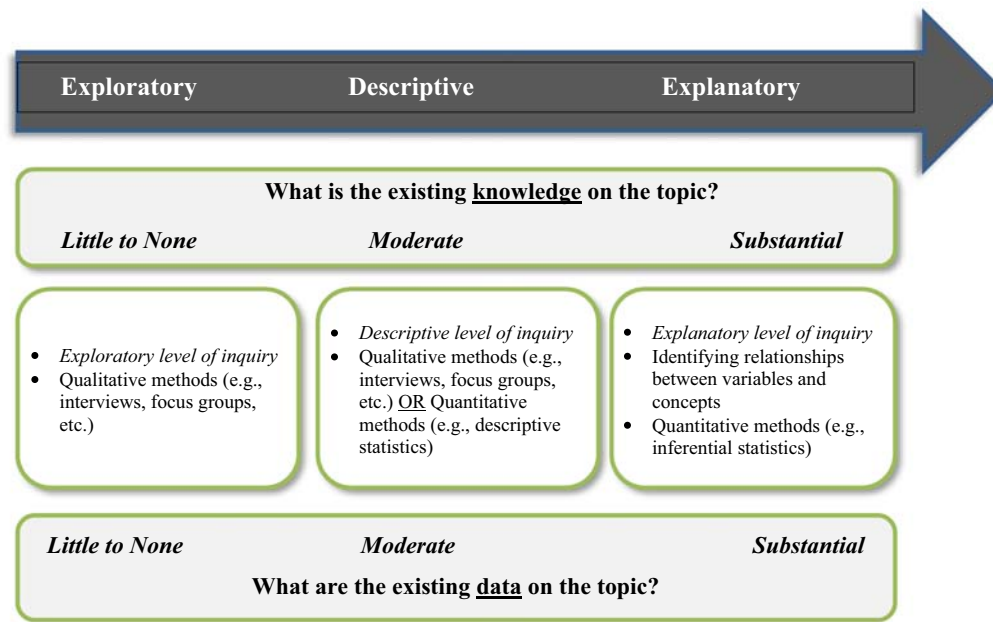

Fig. 2 The knowledge-level continuum as a framework for mixed methods with existing data.

Considering the same example above, let's say Charlie continued their search for peer-reviewed articles that demonstrate students' sense of belonging in virtual learning spaces and cannot locate articles. However, Charlie's faculty advisor sends them eight peer-reviewed articles she found while working on a grant. As Charlie reviews the articles, they are excited to see the articles synthesize a lot of the information they hoped to find. The articles also describe preliminary findings on college students participating in online classes and their sense of belonging. However, none of the articles include results for K-12 students and their sense of belonging in virtual learning spaces during the unprecedented time of the COVID-19 pandemic. In short, there are still some gaps in research that focus on this topic.

In reviewing the knowledge-level continuum, Charlie acknowledges that while *some* information exists on the topic of interest, the existing literature does not extend to cover the specific topic Charlie was hoping to investigate. Given this, Charlie decides that a descriptive level of inquiry would be best. *Descriptive research* is the second level of research within the knowledge-level continuum. It involves expounding on the pre-existing knowledge by describing the sample and concepts of interest in more detail. Descriptive research can be conducted using either qualitative or quantitative methods of inquiry. In the case above, Charlie may use an existing sense of belonging psychometric tool to measure students' sense of belonging in the virtual learning environment.

If the existing literature included substantial knowledge of sense of belonging, specifically for K-12 students that participated in virtual learning during the unprecedented 2020–2021 academic year, then Charlie would use an explanatory level of inquiry for the research. *Explanatory research* is the highest level of the knowledge-level continuum and is conducted using quantitative methods of inquiry because previous data exists on a topic. If Charlie conducted an exploratory study (i.e., first level of the knowledge level continuum) to understand the students' sense of belonging in virtual learning environments and then conducted a descriptive study (i.e., secondary level of the knowledge continuum) to collect more detailed information about students and educators' sociodemographic background and characteristics, then existing data exists on the topic! Therefore, an explanatory study can help Charlie understand the associations between concepts identified in the exploratory and descriptive studies on this topic. Explanatory research studies produce inferential statistics that Charlie can generalize to the larger population.

Applying the knowledge-level continuum to mixed methods with existing data

The knowledge-level continuum can be used as a framework for mixed methods research with existing data because it both informs, and is informed by, how much is already known about the topic of interest. Let's consider an example where a researcher, Marcus, is trying to decide whether to use a convergent, exploratory sequential, or explanatory sequential mixed methods design for a study with existing data (Creswell, 2015; Watkins, 2022). In this example, Marcus wants to use existing quantitative data on SAT scores for Deferred Action for Childhood Arrivals (DACA) students who attend ivy league colleges and universities in the United States.

The first step is for Marcus to search for previous knowledge and data on the topic. He might decide to check Google Scholar, Psych Info, EBSCOhost, and Science Direct for articles that include keywords in the title and abstract. Then, he might finalize his research question (*How do SAT scores for DACA students who attend ivy league colleges and universities compare to SAT scores for other*

DACA students at other colleges and universities at their colleges and universities?). After the research question is finalized, Marcus should consider whether the question is suitable for integrating his existing data with a second, qualitative data source. Marcus must determine which mixed methods design (Fig. 3) will help address his research question. He can do this by examining the research question, the current state of science (i.e., previous knowledge and data on the topic), and the existing data on the subject (i.e., existing data on DACA students' SAT scores).

If Marcus finds little to no existing research on the topic, he has the option to conduct an exploratory sequential design. However, given the variables in his existing dataset, he could likely build a convergent design where the quantitative phase involves analyzing the existing data on SAT scores for DACA students at ivy league colleges and universities. His qualitative phase could include online interviews with a select number of DACA students at ivy league colleges and universities across the United States. Though his existing quantitative data are more descriptive, and he could also conduct an explanatory sequential design, he would prefer to do a convergent mixed methods study where the new qualitative findings can be merged with the existing quantitative data results.

Three questions when choosing existing data in mixed methods research

Before incorporating existing data in your mixed methods research, you must first identify the most appropriate existing data for your project. You may be asking yourself: How do I choose the best existing data for my mixed methods project? Below, we provide three questions you should ask yourself as you review potential data sources.

Question 1: How will you define the terms in your research question?

The first question you should ask yourself will help outline the plan of action for your mixed methods project. When looking at your research question, what does each word mean? In other words, how will you define the terms in your research question for your mixed methods with existing data? Essentially, what you need to uncover is what is under investigation in your study. As you choose specific terminology for your research question, be sure to determine how you will define and measure these terms. The words you use to develop your research question will outline an action plan for your mixed methods with existing data. In the earlier example, Charlie can perform a thorough literature review of students' sense of belonging, then choose terms for their research question that signal the study's exploratory nature. Therefore, Charlie's research question could be *What are the barriers and facilitators to students' sense of belonging in virtual learning spaces?* Looking closely at this research question, we would advise Charlie to highlight words that need a definition and are directly connected to the success of their study. For example, terms such as "barriers," "facilitators," "students," "sense of belonging," and "virtual learning spaces" all need clear definitions. They also need units of measurement as the success of Charlie's mixed methods is contingent upon a deeper understanding of and the ability to measure these terms.

Question 2: How do you plan to find the existing data?

There may be field-specific data repositories for existing data; however, you must actively seek out information to help locate existing data sources regardless of your field of study. The next question you ask yourself should point you toward existing data that will help answer your research question. Begin by asking your mentors, advisors, professors, and classmates for recommendations for data sources related to your well-defined research question. Additionally, use institutional resources, such as academic librarians, to strategize the methods used to search the web and online databases. It is important to note that the more defined your research question is, including your concepts and variables, the easier it is for others to assist with your search. You want to develop a plan or strategy to locate the data at this stage. Which search terms will you use? What strategies (e.g., filters, Boolean connectors) will you use to search across data repositories? What data depositories can you access? In Charlie's case, they could retrieve existing

Fig. 3 Choosing mixed methods designs that inform, and are informed by, existing data and the knowledge-level continuum.

data from their professor, so thankfully, Charlie did not need to look very far to locate existing data. However, it will be necessary for Charlie to closely examine the appropriateness of their professor's existing data to ensure that the research question (*What are the barriers and facilitators to students' sense of belonging in virtual learning spaces?*) can be addressed. This leads us to the final question.

Question 3: Do the existing data help answer the research question?

Now that you have defined the terms in your research question and developed a plan for locating existing data, you must address the final question regarding the appropriateness of the existing data for your mixed methods project. Evaluate the existing data to determine if it has adequate information to answer your research question (Kiecolt and Nathan, 1985; Smith, 2008, 2011). This final question aims to ensure you have thoroughly assessed the fit of the existing data for answering the research question *before* incorporating it into your mixed methods. Go through the existing data, supplemental materials, and any previously published reports on the data so you can learn about the primary study, from conceptualization to evaluation. So Charlie will need to conduct a rigorous review of the variables (if quantitative), concepts reviewed (if qualitative), and all the professor's supplemental materials on file. If there are materials the professor does not have, Charlie should try to locate these materials to help them develop a comprehensive knowledge base about the data. Charlie should be able to answer questions such as: What was the original purpose for the data? How were participants recruited? How were relevant concepts measured? How was missing data handled?

In sum, there are three questions to address when choosing to include existing quantitative or qualitative data in your mixed methods study. This strategic process begins with you asking yourself questions that will help you explicitly define your research question. Next, you must develop a plan to locate existing data that includes the variables or concepts captured by your research question. Finally, once you locate the existing data, you must assess if they meet the needs of your research question. These steps provide a roadmap and an action plan for selecting existing data.

Conclusion

This chapter provides an overview of how mixed methods with existing data can advance education research. The knowledge-level continuum can serve as a framework for your mixed methods study. It describes the research process for all studies, depending on how much is already known about the topic of interest. The knowledge-level continuum is a direct by-product of the existing information on a topic, the purpose of the research, and your anticipated next steps. Using existing data in mixed methods includes identifying, evaluating, and incorporating one or more existing data sources to serve as one or more data phases of your mixed methods. It acknowledges not only the purpose of mixed methods but also the purpose of existing data analysis, which is to further the investigation of an existing data source by addressing a research question similar to (or distinct from) that for which the original data were collected.

Using existing data is advantageous in mixed methods because it allows you to expand your knowledge and understanding of a topic, gauge the qualitative depth of a topic so you know how to proceed quantitatively, and gauge the quantitative breadth of a topic so you know how to proceed qualitatively. Almost any research question in education research would benefit from an existing data source. Access to an existing study's protocols, guidelines, training materials, codebooks, and field notes can make you feel like you were part of the original research team. Therefore, consider locating an existing data source before agreeing to collect data for a new mixed methods project.

Introduction

In this chapter, I introduce Geographic Information Systems (GIS) and its empowering applications in research. GIS is a computer-based tool for mapping, measuring, monitoring, modeling, and managing spatially referenced data. GIS can be considered a database system and a set of spatial visualization and analytic operations for working with such a database. Quantitative and qualitative data can be combined in GIS to produce a fuller understanding of our world. This integration of qualitative data in GIS is called Qualitative GIS (QGIS). In a sense, QGIS may be thought of as a higher-order map in the context of mixed methods research (MMR), as it enables us to overlay different layers of data.

Similar to early proponents of mixed methods research in social sciences, critical and feminist geographers who have advocated for QGIS applications (for early QGIS works see: Pickles, 1995; Schuurman, 2000; Sheppard, 2001; Elwood, 2002; Pavlovskaya, 2006; Kwan, 2004) challenge the dualism separating quantitative and qualitative methods while highlighting the importance of both human (soft) and physical (hard) sciences (Maxwell, 2010; Fielding, 2012). In other words, as Fielding and Cisneros-Puebla (2009) suggest “spatially oriented qualitative social science and qualitatively oriented geography” (p. 349)—known as QGIS in GISciences—are more recent, innovative examples of combining technology with ethnography in mixed methods research handovers. QGIS emphasizes integrating multiple forms of data to create a bigger picture and greater insight into what is happening (and why) in the study area.

This chapter starts by revisiting the definitions of GIS and QGIS. I will then contextualize the application of GIS and QGIS in education, both inside and outside the classroom. Through several examples of classroom activities, I will illustrate how GIS can be used by teachers inside the classroom for promoting interactive learning skills. In addition, I will review a few research case studies in which educational scholars, school administrators, and public policy makers have used GIS to address school districts' academic performance and social (in)justice issues. Next, in order to better illustrate the integration of different types of data in GIS, I will rely on my long-term methodological research combining GIS and ethnographic methods focusing on women's social perceptions and experiences of public spaces in Tehran, Iran. My goal here is to acknowledge the methodological opportunities of using mixed methods approaches such as QGIS by both human and physical sciences researchers. I will examine the advantages and limitations of using QGIS as a mixed methods approach, highlighting the challenges I came across throughout my research project in Tehran. I end the chapter by contending that QGIS is an invitation to scholars in social sciences (e.g., human geography and anthropology) to benefit from GIS spatial visualization and technical analysis tools. It is also a recommendation for hard science scholars (e.g., environmental sciences, geology and physical geographers) to challenge the inherently quantitative, positivist framework of understanding space and to adopt a more mixed method approach in their research.

Defining GIS and QGIS

GIS according to the National Center for Geographic Information and Analysis (see <http://www.ncgia.ucsb.edu/>), is a system of hardware, software, and procedures designed to support the capture, management, editing, analysis, modeling, and displaying of geographically referenced data for solving complex planning and management problems. Key components of GIS include computer hardware (e.g., desktop computers, laptops), specialized software (e.g., ESRI ArcGIS, Online GIS, Free and Open Source GIS web and mobile apps), geographically referenced data (e.g., demographic, social, economic, political, racial composition, household median income), and people who are involved in all phases of making and reading maps. GIS is used to map, measure, monitor, model, and manage spatially referenced data. Overlay tool, or the concept of stacking layers containing different kinds of data and comparing them with each other based on where things are located is the foundational concept of spatial analysis. For

a more visual understanding of a GIS map, as I often say in the first week of teaching Introduction to GIS, it resembles “a multi-layered sandwich made of data,” as shown in Fig. 1. In GIS each dataset is managed as a layer and can be graphically combined with other layers. By combining layers using spatial analysis and visualization operations, GIS enables us to explore critically important questions and possibly find answers to those questions. GIS basically offers a systematic way of overlaying all sorts of datasets together; then, through this superimposed composition of layers, spatial relationship among different layers, spatial patterns, and future trends can be identified, explained, and predicted.

QGIS refers to an array of methodological efforts to incorporate into GIS more qualitative data than was traditionally included. QGIS can also be placed among those post-positivist, poststructuralist, and non-representational approaches in contemporary cultural geography that strive to reconcile “social-cultural and spatial-analytical geographies” (Kwan, 2004, p. 756). Although many feminist and critical geographers (see Pratt, 1989; Sheppard, 2001; Moss, 2002; Kwan, 2002, 2004; Cope and Elwood, 2009) have already challenged the dualism separating quantitative and qualitative geography, innovative mixed methods approaches such as QGIS (that includes geo-ethnography, feminist data visualization, grounded-visualization, and geo-narrative) are still in their early stages. An increasing number of researchers integrated GIS-based spatial visualization and analysis into qualitative methods, such as ethnography. Photographs, sketches, mental maps, social behavior maps, audio and video records, field notes, interviews, and narratives gathered through qualitative methods can be linked to spatially referenced data in GIS software and offer new ways of representing individuals’ lived experiences (Al-Kodmany, 2002; Aitken and Kwan, 2009). For example, McLafferty (2002) narrated a story of how women affected by and concerned with breast cancer used GIS to explore the relationship between environmental hazards and the geographical distribution of disease in suburban Long Island, New York. QGIS were used to map the environmental factors that were correlated to increasing prevalence of breast cancer in their neighborhood as well as qualitative data collected during interviews with the affected women and their community members. McLafferty (2002) concluded that GIS was “more than a computer-based technology” and could not only serve as “a vehicle for women’s empowerment” (McLafferty, 2002, p. 268) but empower other underrepresented populations as well. In another study asserting the value of grounded theory in urban cultural research, Knigge and Cope (2006, 2009) applied what they call “Grounded Visualization” as an integrated method that enabled them to explore spatially referenced data in close relationship to ethnographic and multi-media data for the study of community gardens and the meanings of vacancy in Buffalo, New York.

Cieri (2003) combined 3D GIS and qualitative data to study lesbian public spaces in Philadelphia. What made her successful in such a critical endeavor, however, was her application of mixed methods approach, similar to Knigge and Cope’s grounded visualization. As illustrated from the natural resources management, Nightingale (2003) claimed to go beyond the limitations of partial and situated knowledges imposed on feminist geography by using QGIS in tracing forest change in Nepal. Through her study of gender and individual access to urban employment opportunity in Columbus, Ohio, Kwan (2002), introduced the concept of

Fig. 1 Overlaying different data layers on a GIS map. Source: <https://www.esri.com/arcgis-blog/products/product/analytics/how-to-perform-spatial-analysis/>.

“Feminist Visualization”. Kwan and Ding (2008) and Kwan (2008) were excellent examples of emotional geographic studies in which the “Geo-narrative” method—integrating GIS’s spatial analysis and narratives—was used to examine the effects of anti-Muslim hate violence on Muslim women’s lives in Columbus, Ohio, in the post-September 11 period. In another study, Watts (2010) reconciled on-the-ground qualitative data with point-distribution GIS data to investigate participants’ socio-spatial behaviors in Los Angeles’s public protests. Jones and Evans (2012) encouraged mobility scholars to take advantage of QGIS application to better examine the role of space in data creation.

Coupling GIS techniques with ethnographic methods was also referred to as “Geo-ethnography” by Matthews et al. (2005) in their ongoing study of low-income families and their children and welfare reform in Boston, Chicago, and San Antonio. While examining job accessibility among working poor members in Columbus, Ohio, and feelings of safety among Lesbian, Gay, Bisexual, Transgender and Queer people in St. Louis, Missouri, Boschmann and Cubbon (2014) digitized and transformed qualitative sketch maps using GIS. Sketch maps are subjective, hand-drawn outlines of people’s observation and perceptions and are not from exact survey measurements. They concluded that, while such a process is time consuming, it can achieve QGIS’ objective of “collecting unique spatial data of individual experiences, visualizing socio-spatial processes, breaking down particular barriers of positionality in research, and developing new uses of GIS” (Boschmann and Cubbon, 2014, p. 3).

QGIS can be considered an umbrella term for the mixed methods approaches described above. “The qualitative” can be associated with the qualitative nature of either the data gathered (e.g., interviews or sketches) or the analytic methods used in the research (e.g., content analysis, triangulation, and grounded theory) (Jung and Elwood, 2010, p. 67). Despite different approaches of integrating multiple forms of data, this review of literature highlighted the common theme of creating a bigger picture and greater insight into the current research in this area. These approaches can also empower political research methods, through which the stories of subaltern and/or marginalized groups including women, children, the disabled, LGBT, racial, and religious minorities can be heard and included in the research process. Often, these methods are used in community-based and participatory planning projects where a deeper understanding of context and the groups who are being represented is essential. QGIS—like any other mixed methods approach—can improve our understanding of space from rigid to fluid, through including ethnographic data such as people’s experiences. In this approach, research becomes truly an open-ended emergent process and partial, contextual, and situated (Haraway, 1991) rather than the set of predictable determined steps often advocated by GIS scientists. In what follows, I discuss the use of QGIS as a mixed methods approach in education and present a case study of using QGIS in a research project conducted in Tehran, Iran, an examination of women’s social perceptions and experiences of public spaces, and their symbolic interpretations of modern and traditional public spaces developed by urban planners. This case study is not intended to present a full account of women’s conceptualization of modern and traditional public spaces in Tehran, but rather to illustrate how QGIS can be applied as a mixed methods approach.

Using QGIS as a mixed methods approach in education

Research over the past two decades has emphasized the value of story mapping and geo-narrating in scientific communications for non-expert audiences as well as teaching science to the students in all levels of educational system (see Drennon, 2005; National Research Council, 2005; Bodzin and Anastasio, 2006; Artvinli, 2010; McCloughlin, and Matthews, 2012; Hong, 2014; Kerski, 2015; Patterson and Bickel, 2016; Cope et al., 2018; Chrysi and Mark, 2019; McCrudden and Marchand, 2020.).

To highlight GIS application in classroom, Cope et al. (2018) developed an ESRI Story Map called “Soil Forming Factors: Topography” for teaching an introductory soil science course at Clemson University in South Carolina. The objective of this story map was to introduce students to topography as one of the five soil-forming factors. Elevation, slope, aspect, and landscape position were interrelated elements of topography as a soil-forming factor that were traditionally taught using topographic maps or instruments in the field. In this innovative usage of ESRI Story Map, the research team introduced students to these elements via interactive web maps. The team assessed the performance of the newly developed Story map and students’ learning from Story map based on their responses to a quiz. Specific learning objectives were stated on each story map and throughout the learning materials. Highlighting the benefit of mixed methods, students used already-collected qualitative and quantities data in their mapping. The research team found out that overall, students were receptive about the ESRI Story map as a stand-alone teaching tool or in combination with PowerPoint slides. They suggested that their new Story Map could be further improved by incorporating interactive exercises.

In another example of using web-based GIS in classroom, fifth graders at the Zilker Elementary school in Austin, Texas engaged in a hands-on experiential online mapping project using free version of Social Explorer platform to explore the neighborhoods they live in. Students were able to switch among different data layers such as population density, racial composition, and the average age of buildings. Students were able to observe the formerly invisible associations, patterns, and tendencies in their local communities. In addition, GIS enabled students to construct reports, tables, and graphs of the given data. The educators concluded that the interactive GIS assignment was useful in creating awareness and sharing knowledge regarding the environment, communities, and social resources. Both these examples confirmed GIS can be used as an effective teaching tool in the physical and social sciences education. However, in both cases, students and teachers suggested more data to be added to their maps, particularly qualitative data. Additional qualitative and perhaps intangible data layers were important for students to understand the concepts they were learning in a more holistic, engaging, and realistic manner. This integration of qualitative data in GIS is what advocates of mixed methods research call QGIS.

With my background in academics and a major in non-education, I readily advocate for the applications of GIS in the current mixed methods approaches in educational research. Spatial visualization and analytic techniques are powerful and empowering in physical and human sciences. GIS methods provide further insights into several aspects of education and offer new opportunities for teachers to apply learner-centered methods in an engaging manner. The applications of GIS in and outside the classroom is summarized as follows:

GIS as a teaching tool in the classroom

GIS—particularly its more-user-friendly Environmental Systems Research Institute (ESRI) Story Map tool—has been considered as a research tool in the classroom for students and teachers studying diverse concepts in a variety of disciplines, not only in geography, but in history, mathematics, language arts, environmental studies, chemistry, biology, civics, and many more. According to ESRI (see <https://www.esri.com/arcgis-blog/products/uncategorized/uncategorized/story-maps-101/>), “Story map uses geography as a means of organizing and presenting information. They tell the story of a place, event, issue, trend, or pattern in a geographic context. They combine interactive maps with other rich content—text, photos, illustrations, video, and audio—within intuitive user experiences.” In other words, Story maps are web applications that allow students and teachers to combine web maps with narrative text, images, and multimedia, including video and audio. These applications are designed to be attractive and useable by anyone, which makes them great for education and outreach to the general public or to a particular audience.

This application happens at all levels including primary and secondary grades and continues to college and university courses. The GIS maps or Story Maps created by students offer both problem-based learning (PBL) and inquiry-based learning (IBL). “GIS as one of the 21st Century communication tools will assist in nurturing students’ abilities in investigating, evaluating, integrating, creating and analyzing issues and information at various scales and locations.” (Kibetu and Jackson, 2019: p. 202). Using mixed methods such as Story Map enables students to learn environmental analysis and problem-solving skills in a multi-layered and interactive visual way. This helps students think critically about the spatial relations among different layers, use real data, and connect them to their own communities. Because of its multi-layered, interactive spatial nature, the GIS application by students in the classroom can increase students’ curiosity, enhance learning capacity, and advance map literacy. In addition, GIS application enables teachers to emphasize concepts in different and relatable ways and adapt learning experiences to meet the needs of all learners.

GIS as a research tool outside the classroom

GIS can be used as a research tool by decision-makers, school administrators, counselors, and educators outside the classroom. The city may use GIS to redefine or adjust school district boundaries with respect to changing urban demographics. Schools may use GIS to plan access to facilities and to design new facilities and resources (e.g., technology lab, room allocations, and science lab). In addition, GIS visualization and analysis may help administrators to understand the relationship among students’ performances, the school district’s social and demographic status, and students’ access (or the lack thereof) to resources. These spatial understandings may decrease the long-standing inequity and accessibility gaps among different neighborhoods of a city. School administrators and teachers may use GIS to plan recruiting students, arrange extracurricular and after-hours activities, and manage alumni networks. On the other hand, GIS can also help the students, teachers, and school staff to become more spatially aware of the school (e.g., safe rooms, exits, or escape routes) and prepare for an emergency. GIS offers administrators a way to visualize and manage everything from monitoring campus safety, mapping campus buildings, cable and other infrastructure, routing school buses, planning where and when to close schools and open new ones, and strategizing recruitment efforts. GIS provides educational policy-makers with tools to examine spatial patterns and relations among educational achievement, school performance, racial and class inequalities and where to target new programs (see Taylor, 2007; Miller, 2012; Wei et al., 2018; Smith et al., 2019).

Traditionally, educational research is driven by qualitative designs such as ethnography, phenomenology, grounded theory, narrative, and case study. However, GIS visualization tools can be used to overlay different layers of data, including school rankings, students’ educational performance, school districts’ demographic characteristics, the socioeconomic status of the neighborhoods, levels of parents’ education, assigned governmental funding. Applying GIS spatial analysis tools, one can also illustrate any potential spatial clustering, patterns, and relationship among the above-mentioned factors. Recent studies in mapping social inequalities have highlighted the strong relationship between schools’ locations and the relative advantage or disadvantage of the neighborhoods in which schools are located. Research on neighborhood context on educational outcomes can benefit from GIS applications in order to better understand educational inequality. In addition, qualitative data such as interviews and/or participatory mapping by students, teachers, and parents can add a nuance dimension to GIS maps.

Given the advantages of using GIS in educational settings, there is a rationale in employing GIS mixed methods approach in exploring socio-cultural and geopolitical issues of a region or a nation. In the case study that follows later in this chapter, I rely on one innovative application of QGIS in geographic research in a non-western context. I draw on the methodological component of my ongoing geographical research on women’s social perceptions of and experiences in Tehran’s public spaces, the process that is highly gendered and classed. Photographs, sketches, and narratives collected from women in Tehran, Iran, were linked to GIS data gathered from the Iranian Census Organization, National GIS Database, and Tehran Municipality. This case study contextualizes QGIS applications in perhaps an unfamiliar cultural and political setting and therefore facilitates examining its limitations. The intensive literature review and findings from the case study illustrate not only the opportunities QGIS introduces to researchers

but also the boundaries of the technology at its current level. Through this case study based on QGIS application, I aim to invite more educators and educational scholars to take advantage of powerful and empowering qualities of GIS.

An application of QGIS: Women's perceptions and experiences in Tehran's public spaces

This section is written from a feminist geographer's perspective in which mapping is seen as a subjective, geopolitical tool reinforcing global and local hierarchies. Therefore, while GIS can open new avenues of knowledge to researchers by aiding in analyzing the spatial and social contexts of research subjects, it still emphasizes the significance of using ethnographic methods. GIS provides educators, researchers, and policymakers an empowering decision-making tool that can be used in educational administration and policy, and teaching. However, the integration of GIS tools with qualitative data becomes even more essential in educational research as we study different human subjects (e.g., students and teachers), their identities, perceptions, relationships, access to resources (or the lack thereof), and finally the art and science of teaching and learning.

To emphasize the differences between social construction of public spaces in non-Western and Western contexts and to understand Muslim women's socio-spatial behaviors in public spaces, I studied women's social perceptions and experiences of public spaces in Tehran, Iran (see Bagheri, 2013, 2014a,b, 2020). One of the main reasons I chose to focus on female users was the societal norms and my own positionality. As a female researcher, I found it more feasible to approach and talk with women than men. In addition, having grown up in Tehran and being familiar with local symbolic politics, I approached women in public spaces as a researcher, collected and interpreted their narratives. For instance, I chose to wear a typical academic/student hijab (*Maghnae*) instead of a more relaxed everyday hijab (*Roosari*) during my field visits. My research assistant (a fellow graduate student at Tehran University) and I approached women by introducing ourselves as scholars and users of public spaces. We explained how our research findings could benefit women like our interviewees through designing and managing public spaces.

The goal of this fieldwork was to illustrate how modern public spaces (e.g., shopping malls that were often located in Tehran's northern neighborhoods) and traditional public spaces (e.g., bazar and squares that were often located in Tehran's southern neighborhoods) in Tehran were used by women. However, the women's narrative did not recognize this often-used binary categorization of modern and traditional public spaces by urban professionals. Modern and privatized public spaces in North American contexts have been criticized for their highly commercialized atmosphere, controlled behavior and design, and segregation of certain racial and class groups (see Soja, 1989; Sorkin, 1992; Crawford, 1992; Banerjee and Loukaitou-Sideris, 1992; Zukin, 2003). Critics suggested that the privatization and modernization of public spaces which are standard designs have reduced them to more exclusive places and negatively influenced the social life happening in them. I selected two public spaces in Tehran with contrasting locations, functions, and architectural designs to examine these criticisms in a non-Western context. While there was not a clear boundary between traditional and modern public spaces according to the women with whom I interacted, the selected public spaces' contrasting locations in Tehran (one in the very northern and one in the south-central part of the city), their socio-political history, as well as their architectural designs and functions, allowed me to represent and comparatively study a more modern and a more traditional public space.

The case study pursued a mixed methods approach with a rich ethnographic quality and took advantage of socio-spatial data visualization and analysis in GIS. A mixed methods approach was driven from the fieldwork and became useful because of the nature of research questions. A qualitative-quantitative dichotomy seemed inadequate in understanding the complex relationship between women's social perceptions and experiences of public spaces, and the design and location of such places. Even in my very first round of participant observation, I noticed that both qualitative and quantitative characteristics of public spaces influenced women's presence and preferences. I collected and analyzed several layers of qualitative and quantitative data (see Fig. 2).

I used diverse methods of data gathering that were based on the socio-spatial experiences of women's everyday lives. I followed Lofland and Lofland's (1994) suggestion and began fieldwork visits with short-term covert participant observation. This gradual, "bottom-up" process let the research interests and questions grow from the field itself, rather than from theory. First, I collected photographs (qualitative data) to illustrate visual details such as women's style of hijab and make-up, and created spatial behavior maps to track women's numbers, activities, and locations as well as characteristics that are readily observable, such as approximate age, sex, and whether the individual was alone or in a group. As another qualitative data, I also drew architectural sketches to capture

Fig. 2 An application of QGIS in mapping women in Tehran's public spaces. Maps created by the author.

a sense of place. In addition, I conducted in-depth semi-structured interviews with 83 women who were using two seemingly contrasting, modern and traditional, selected public spaces in Tehran.

The women talked about their feelings, experiences, and preferences in those public spaces. I examined different ethno-cultural and symbolic meanings women attached to these public places. In contrast to the predominant critique of modern public spaces in the literature, I observed that Iranian women enjoyed a unique sense of freedom and equity with men in Tehran's modern and semi-private public spaces. Women narrated how they felt more comfortable doing certain activities such as holding hands with their boyfriends, smoking, talking louder, or laughing in modern public spaces when compared to more traditional public spaces. Women's narratives and hijab details gathered during participant observation also suggested that women had more freedom in their hijab and dressing styles in more modern public spaces; many interviewees emphasized that they would put on more make-up and fashionable, colorful clothes in such places. However, women's responses indicated favorable opinion of both public spaces, although for different reasons. Women's narrative and experiences suggested that they enjoyed a sense of freedom in the more modern public space while appreciating a sense of nostalgia and connection to their Iranian-Islamic identity in the more traditional one, such as Marvi Meidancheh (see Fig. 3). Fig. 3 illustrates an integration of qualitative data and quantitative data in a mixed methods approach, that is, an overlay of women's selected narratives, photographs, sketches, and dot density (produced in GIS) of women vs. men users in Marvi public space.

Advantages and limitations of using QGIS as a mixed methods research approach

While QGIS offers a valuable approach to many studies that deal with the concept of space and socio-cultural production of space, it is neither easy nor complete. Similar to any other MMR method, it is important to be aware of the potential limitations of QGIS, particularly due to the rapid pace of GIS software capabilities and accessibilities. In what follows, I offer a critical examination of the limits of QGIS in the case study while briefly reviewing its merits. Benefits include data management, discovery of spatiality of social processes, and an emphasis on the importance of ethnographic data in cultural geographic research. Limitations consist of potential data exclusion and data scale incompatibility.

In the above-explained research project, I used GIS to integrate qualitative and quantitative data gathered in the field. I first digitized the spatial behavior maps and transferred the population counts to GIS maps. Using Overlay, arguably the most important GIS

Fig. 3 A Mixed Methods Approach: Combining qualitative and quantitative data in GIS. Map created by the author.

analysis function, I examined the relationship between different demographic and socio-economic data layers gathered from the Iranian Census Organization, National GIS Database, Tehran Municipality, and population counts by gender on maps. I used the Kernel Density Estimation tool in GIS to illustrate female and male density and spatial distribution on maps. The maps showed interesting spatial patterns of female and male users in selected public spaces; however, they did not explain why such patterns existed. For instance, both the geo-visualization and statistical spatial analysis done within GIS software suggested that women in the more modern public space were less segregated from men compared to those in the more traditional one. In the absence of any regulations regarding male and female users' segregation in any of those public spaces, why did GIS maps suggest such spatial segregation? The GIS results also suggested the density of female users were relatively similar in both public spaces, particularly on weekends when the places witnessed their highest percentage of female users. How did the differences in design, location, and more importantly, attached symbolic meanings influence women's social perceptions and experiences of public spaces between these two public spaces? The supplementary women's narratives and field notes were useful in explaining these findings. Through talking with women, I examined their ways and values, and it became clear that "culture ... is at the heart of everything" (Mitchell, 2004, p. 155). Women attached different symbolic and ethno-cultural meanings to the selected public spaces that influenced their presence and behaviors in places.

Meanwhile, I created a geodatabase to record the location of each interview and to store the interviewee's characteristics (such as age, education, and home location). Using data management tools such as Query and Attribute Table in ArcGIS allowed me to be more organized in the gathering phase. For instance, I digitized the location of each interview to a Point Feature and used the hyperlink tool to connect the point to qualitative data I gathered in the field (e.g., key points of interviews and field notes). Watts (2010) found it difficult to "map" sounds of riots in Los Angeles, however, for me it seemed feasible to map narratives as I was concerned more with the women's narratives, rather than the background sounds in public spaces. However, I encountered different challenges in mapping my narratives. For example, women named different places, similar or contrasting to the one they were in, to further explain their feelings and preferences. This raised several questions: Was mapping narratives to the specific interview location enough? Would it be feasible to include the names of other places referenced in the interviews on GIS maps without actually being there or studying them? Would that be a useful or even readable map? What kinds of data gathered during field observation and interviewing could be transformed into GIS? Basically, the question was to what extent the rich and complex qualitative data, such as interview transcriptions, were transferrable into quantitative GIS codes and symbols. Examining possible answers to these types of questions, Jung and Elwood (2010), recognized what can be deemed an inevitable disadvantage of QGIS, potential data exclusion, and argued that "a host of other potentially significant details are lost" (p. 68) in the transformation process.

A similar challenge appeared when we considered the meaning of visual and spatial representation, one of the most exciting prospects of QGIS reported in earlier celebratory works on bridging the qualitative and quantitative domains. To this end, hyper-linking was enough for storing data but not for visually representing it. To represent ethnographic data, I included summarized and chosen data from each interview on maps. That means I had to choose which data was more important to be included on maps. This emphasized that GIS is not an independent tool; rather, it becomes part of the storytelling itself. In other words, in the process of "embedding" the individuals' lived experiences, the GIS user's agency (his or her personal characteristics and research goals) and the specific spatial analysis tools used affected the reality being represented and consequently the research results. While GIS can incorporate diverse forms of data, this case study illustrated the two worlds of complex reality and GIS representation cannot be seamlessly overlapped. Here, I questioned Krygier and Wood's claim (2005) that "you can map just about any data you can collect from the environment" (p. 51). I suggest that you may map almost all types of data, but not necessarily in an inclusive, efficient, and/or meaningful way. There remain some realms of human experiences and stories that are not "mappable," in a meaningful manner, at least not with current GIS technology. For example, women showed specific facial expressions and other body languages when they talked about their feelings in public spaces. How women felt while we were talking, why they attached certain symbolic meanings to those public spaces, or how such meanings changed their presence and behaviors are just few examples of qualitative data that cannot be mapped in GIS. This highlighted the importance of ethnographic data in cultural geographic research.

The second limitation I experienced with QGIS was data scale incompatibility. It is argued that QGIS allowed researchers to link pre-existing datasets (e.g., from censuses) to one's specific dataset (Bell and Reed, 2004; Jung and Elwood, 2010). However, this linkage can be meaningful or meaningless considering the difference among dataset scales. In my case study, the data gathered during participant observation and interviews were space and time sensitive and were based on individuals' opinions while the background GIS data (e.g., Census) were prepared based on official urban planning, social, and/or demographic data that were gathered and normalized at either *mahaleh* (neighborhood), *mantagheh* (districts), or the city of Tehran. I found it difficult and sometimes impossible to analytically link qualitative data to quantitative data layers in GIS considering their different scales. For example, while there could be a relationship between the interviewee's hijab style and her age, education, and median household income; there was not any meaningful relationship between her hijab with the similar data aggregated at the level of the district in which I interviewed her, or even at the level of the district in which she lived. Multiple GIS representations of different data can lead to wrong conclusions, in this case, to a wrong correlation between women's hijab and the quantitative attributes of the district where the interviews were conducted (particularly, for non-local scholars that may not be familiar with the symbolic politics of hijab in Iran). This data scale incompatibility can cause a major challenge in the data analysis phase because GIS application can both facilitate and hinder efforts to represent complex social and spatial realities. While Knigge and Cope (2009) found it useful in their case study, linking GIS and ethnographic data gathered at different scales was not always helpful or even meaningful in my case study. Therefore, I suggest caution in overlapping often quantitative census, urban planning, and land use data that are gathered by the

census organizations, city and district governments, or other state officials with qualitative data collected by a researcher for scholarly purposes. Depending on one's research questions, this capability of QGIS can become an advantage or disadvantage.

I am by no means suggesting GIS and particularly Qualitative GIS applications are not useful in understanding complex social and spatial phenomena, patterns, or processes. On the contrary, I acknowledge the advantages QGIS can offer to researchers, particularly in public participatory planning projects by giving voice to under-represented groups. In my case study, the geo-visualization capability of QGIS clarified that the specific geographical locations of selected public spaces (one in northern and one in south-central Tehran) played important roles in the symbolic meanings and ethno-cultural values women attached to them. In addition, users' spatial patterns on GIS maps also pointed out new aspects of public spaces and led me to modify my interview questions for the next round of field visits. For example, I did not question women about how they felt about their movements in a place, with regard to male users, in the first round of my interviews. But after I observed a spatial segregation in the more traditional public space on GIS maps, I added new relevant questions to my interviews. Indeed, QGIS enhanced and in some cases expedited my data interpretation and analysis, and allowed me to see more, but not necessarily "all." In the next section, I aim to contextualize the application of QGIS in mixed methods research in education, both inside and outside the classroom.

Conclusion

In this chapter, I introduced QGIS as a potential mixed method approach in social sciences. By combining qualitative data often gathered in detailed, contextualized, ethnographic manners and quantitative data often collected systematic, standard, and generalizable ways, one can potentially bring the subjective to the objective in understanding what (and why) is happening and potentially see more. QGIS as an innovative mixed methods approach emphasized the geographical and spatial dimension of phenomenon and processes. Hence, QGIS can offer both educational researchers and educators a powerful and empowering tool. Through an example of QGIS in my examination of women's social perceptions and experiences of public spaces in Tehran, Iran. In this research, I explained how I combined quantitative data such as socioeconomic, political, and religious status of neighborhoods, the geographic location of selected public spaces, the number of women using selected public spaces, with qualitative data including the photographs of women's hijab, architectural sketches of selected public spaces, women's narratives collected during open-ended interviews and my notes during participant observations in the field. These data were transformed to GIS platform, overlaid and analyzed. While the neighborhoods' characteristics and geographic location of the selected public spaces affected women's social perceptions and experiences, the qualitative data (e.g., women's narratives) explained why such spatial patterns were seen on GIS maps. Iranian women were using both traditional and modern public spaces for different reasons; GIS maps accompanied by ethnographic data emphasized the spatiality of social behaviors, in this case, women's social perceptions and experiences in selected Tehran's public spaces. In addition to advantages of using QGIS, I pointed out two potential disadvantages of combining data in GIS, that is, the scale incapability and potential data exclusion. There are ongoing progress to address these disadvantages in QGIS, but we have not yet fully overcome of the GIS limitations in visualizing qualitative data.

I encourage scholars from various disciplines interested in spatial visualization and analysis to consider the limitations of these methods while enjoying its empowering advantages.

"Digital technology [including GIS] can ... reduce critical reflection on the enhanced slippage occurring between map, experience, and context," (Jackson, 2008, p. 346) however, I believe that scholars' recent endeavors in thinking out of the box and acting innovatively to make GIS more accessible to diverse participants are admirable. Similar to the reflections King et al. (1994) made on combining qualitative and quantitative methods, my QGIS application has highlighted the challenges of either technologically impossible or epistemologically meaningless "quantifying" of the qualitative data.

This chapter contends GIS as "a powerful mediator of spatial knowledge and a powerful social actor," (Pickles, 2006, p. 763) expanding our epistemological and methodological horizons and elevating our geographical imaginations. QGIS as an innovative, inclusive mixed methods approach invites us to reimagine the complex, fluid, and diverse nature of human sciences. The application of QGIS encourages scholars to reengage with the political dimensions of knowledge production (e.g., knowledge by whom and for whom). Wood (1992) argued GIS is often used to promote distinctive interests or convince others; however, he emphasizes the interest can be anyone's, including researchers' and researched groups'. In sum, mixed methods approaches including QGIS can give voice to those under-represented groups that are often the subjects of studies conducted by feminist/critical geographers. Without any doubt, QGIS, compared to traditional applications of GIS, promotes more and crucial engagement with the people who are being studied than using solely GIS or solely ethnography.

Acknowledgments

I started writing this paper during the COVID-19 pandemic; meanwhile, I lost my dear friend and graduate student, Mr. Eliberto Vela to this virus. Several people have cared for and supported me during the last couples of years, I am so grateful for their unconditional love and acceptance. Also, I cannot thank the Elsevier staff members of the International Encyclopedia of Education enough for believing in me to finish the project. Dr. Nataliya Ivankova and Ms. Paula Davies were patient, understanding, persistent and encouraging. This contribution would not be possible without Dr. Ivankova's constructive comments and dedication to the subject.

Introduction

A mixed methods research synthesis is defined as a systematic literature review that provides a synthesis of existing knowledge and research evidence on a certain phenomenon by applying the principles of mixed methods research at the meta-level (Heyvaert et al., 2017; Heyvaert et al., 2011, 2013b). These principles are based on the premise that many complex real-world phenomena have both qualitative and quantitative features and that an integration of methods for synthesizing qualitative research and for summarizing quantitative research has an added value as compared to a mono-method approach (Harden and Thomas, 2005; Pluye and Hong, 2014; Sandelowski et al., 2006). Because education as a field of scientific inquiry is concerned with complex real-world phenomena and because a large diversity of scientific disciplines is involved –going from philosophy of education to educational neuroscience– it is expected that mixed methods research synthesis might be well suited as an approach to systematically review educational research.

This article discusses the need for literature reviews, the need to perform these literature reviews in a systematical way, and the need to include both quantitative and qualitative material. In addition, ontological and epistemological issues are presented as a potential pitfall for a mixed methods research synthesis. The article concludes with an overview of the different steps and decisions that have to be taken in a mixed methods research synthesis, the application of mixed methods research synthesis in education, and a worked-out example from educational research.

The need for literature reviews

The increasing number of scientific articles and books makes literature reviews indispensable (Snyder, 2019). When policy makers, practitioners, and researchers want to learn about the state of the art regarding a particular phenomenon or a specific research problem, it is way more efficient to read a topical and authoritative literature review than to be swamped by all separate studies published on the phenomenon or problem. For policy and practice, time is a solicitude, and looking into the scientific literature should be functional for an evidence-based recommendation, a short-term decision, or a prompt (plan for) intervention or action. Literature reviews are ideally suited to fit that purpose. For researchers, reading a literature review provides a first orientation regarding a research problem and can help to avoid reinventing the wheel. Of course, researchers are not only consumers of literature reviews, but also active producers. Conducting a new literature reviews is often described as a first step in the empirical cycle or as a research method on its own for building a comprehensive conceptual model and theory (Hart, 2018).

Although scientific literature reviews can already be found in the 18th century, it is only in the 20th century that scientists started developing methods to improve the reliability and the validity of those reviews (Chalmers et al., 2002). This development was triggered by acknowledging that the sheer number of articles and books entails the risk that a review author, possibly guided by his own predilection or by his eagerness to write a coherent narrative, is highly selective in his reading and digesting of the literature. By being selective, a review author might be prone to draw imprecise or one-sided conclusions, and might instill a biased perspective in the readers of the literature review (Clarke and Chalmers, 2018). Consequently, the need for literature reviews resulted in a need for *systematic* literature reviews.

The need for systematic literature reviews

Lasserson et al. (2021) define a systematic (literature) review as an attempt “to collate all the empirical evidence that fits pre-specified eligibility criteria in order to answer a specific research question” (section-1-1 para. 2). The methods for such a literature review are described as “highly structured” (hence systematic), “transparent”, and “reproducible”, and “are selected with a view to minimizing bias, thus providing more reliable findings from which conclusions can be drawn and decisions made” (section-1-1 para. 2). The reference to “more reliable” in this quotation implies a comparand and is left implicit, but it is clear that a traditional narrative or unsystematic review without pre-specified eligibility criteria is targeted.

Meta-analysis, a term coined by the educational researcher Gene Glass in the 1970s, is a well-established part of such a systematic review and is concerned with summarizing the quantitative information that is available in the articles and books that deal with the systematic review’s research question (Booth et al., 2016; Gough et al., 2017). The “meta” in the term refers to the fact that the analysis usually involves a statistical analysis of the statistical analyses that have already been conducted by the authors of the primary-level studies.¹ In that way, “meta-analysis” is a statistical analysis at the meta-level (Borenstein et al., 2009).

However, not all parts of answers to research questions or solutions to problems are quantitative or quantifiable. Some parts might be intrinsically qualitative, for example evidence and arguments with respect to feasibility, appropriateness, and meaning (Pearson et al., 2005). This poses a challenge for the systematic reviewers: on the one hand they have the highly formalized meta-analytical toolbox at their disposal and on the other hand they might have collected tons of qualitative material about the theoretical background, the history, ethics, politics, and practical implications of the phenomenon of interest. What to do? Ignore the qualitative material? Perform a traditional narrative review of the qualitative material and glue it to the meta-analysis? Fortunately, in recent years, we witnessed the development of several qualitative meta-synthesis methods for summarizing qualitative primary-level studies and for generating new insights and understanding from interrelated qualitative research findings, such as formal grounded theory (Eaves, 2001; Kearney, 1998, 2001), meta-ethnography (Britten et al., 2002; Noblit and Hare, 1988), thematic synthesis (Thomas and Harden, 2008), and meta-aggregative synthesis (Hannes and Lockwood, 2011). Such qualitative meta-synthesis methods can be combined with quantitative meta-analysis methods to arrive at more comprehensive systematic reviews.

The need for mixed methods to conduct a systematic literature review

This combination of qualitative meta-synthesis methods and quantitative meta-analysis methods, however, poses a next challenge for the systematic reviewers: how to combine these qualitative and quantitative methods. Is a juxtaposition sufficient? Or should they aim for an integration? The answer to these questions can be found by going back to the original phenomenon and the research problem of interest, but above all, these questions suggest that insights from mixed methods research can also guide us with respect to performing comprehensive systematic reviews. To wit, the juxtaposition-integration question is at the core of mixed methods research methodology (Bryman, 2007; Creswell et al., 2003; Plano Clark and Ivankova, 2016). This brings us to the application of mixed methods to conduct a systematic literature review: a so-called “mixed methods research synthesis” (Heyvaert et al., 2017; Pluye and Hong, 2014; Sandelowski et al., 2012).

The need for mixed methods research synthesis will be felt most if the phenomenon or the research problem of interest is complex, consists of multiple components and layers, and if quantitative and qualitative aspects can be identified *a priori* (Ferguson et al., 2020; Hong et al., 2020; Noyes et al., 2019). Ideally, the use of mixed methods research synthesis is preplanned rather than incidental. However, it cannot be ruled out that after conducting a meta-analysis, the statistical results for certain moderators are difficult to interpret, there is concern about relevant qualitative empirical evidence that was not included in the meta-analysis, or there are still other qualitative issues that have to be resolved. In such circumstances, a mixed methods research synthesis comes as an after-thought, but is nonetheless worthwhile to consider. Furthermore, in our experience, meta-analysis is rarely a mere mathematical exercise that produces effect size estimates and confidence intervals. Usually there is uncertainty beyond the width of the

¹In order to make a distinction between a review study and the studies on which the review study is based, the latter are commonly called “primary-level studies”. The review study is called a “secondary-level study” or a “study at the meta-level”.

confidence intervals, there are contextual factors that have to be taken into account to qualify the interpretations, and there are qualitative considerations of generalizability that have to be discussed to put the results in perspective. Consequently, some notion of mixed methods research synthesis might be beneficial for every meta-analyst and every systematic reviewer.

In addition to this general benefit, there are four conditions that are particularly conducive for engaging in a mixed methods research synthesis (Heyvaert et al., 2017):

1. If the phenomenon or the research problem of interest does not only consist of multiple components and layers, but if the focus is also on how these components and layers are related, and how these components and layers interact,
2. If the mixed methods research synthesis is carried out in the context of evaluating an educational, behavioral, or medical intervention, and the focus is not only on the effectiveness of the intervention, but also on its feasibility, appropriateness, and meaningfulness,
3. If some of the primary-level studies are already mixed; in that case, those studies can be smoothly integrated with the quantitative and qualitative studies; otherwise, those studies have to be left aside or artificially dissected in a quantitative and a qualitative part, and
4. If qualitative syntheses and quantitative meta-analyses on a topic are already available; in that case the mixed methods research synthesis can act as the scene where the two strands of evidence are combined, possibly updated by new primary-level studies, either confrontationally or complementary.

Notwithstanding the benefits and the opportunities, several hazards for mixed methods research synthesis can also be identified (see e.g., Heyvaert et al., 2017). These hazards are in one way or another related to the major pitfall: ontology and epistemology.

A pitfall for mixed methods research synthesis: ontology and epistemology

Ontology refers to the philosophical study of “what is”; a theory of reality. Epistemology refers to the philosophical study of “what can be known”; a theory of knowledge (Hathcoat et al., 2018). In scientific research, ontology and epistemology play a key role in the research questions being asked, the kind of methods and techniques being applied, and the kind of conclusions and interpretations considered valid or worthwhile. Especially researchers in the qualitative tradition emphasize the relevance of this perspective on the world and on knowledge in the research process, and they recommend that researchers be explicit about their ontological and epistemological stance (Ravitch and Carl, 2019; Savin-Baden and Major, 2013).

Simplifying a complex philosophical debate, ontological positions toward research are often located on a continuum with on the one end the realist position and on the other end the idealist position. Researchers taking a realist position consider reality as singular, concrete, external, and existing independent of the researcher, whereas researchers taking an idealist position consider reality as a social construction, that is at least partially, a product of human perception and imagination, implying the existence of multiple realities (Morgan and Smircich, 1980).

Epistemological positions may be closely related to these ontological positions. On the one hand, the post-positivist position holds that empirical primary-level studies can be valid sources of knowledge about the external world and that it is possible to accumulate this knowledge by verification and falsification. On the other hand, the interpretative position holds that phenomenological insight about the multiple realities can be obtained by hermeneutic methods and critical reflection (Moon and Blackman, 2014).

The crux for mixed methods research is now that quantitative researchers lean toward the realist post-positivist position and that qualitative researchers lean toward the idealist interpretative position (Sale et al., 2002; Savin-Baden and Major, 2013). This makes the endeavor of a mixed methods research synthesis sometimes a hard nut to crack. Not only at the level of the primary studies incompatible world and incommensurable knowledge views might be at stake, but also at the meta-level some common ground has to be found.

The way out can be found by relying on one or more of the following four interrelated approaches:

1. The first approach is that the realist post-positivist position and the idealist interpretative position, as described above, are extremes on a continuum of positions (Howe, 1988; Newman and Benz, 1998). If researchers position themselves more in-between, then combination and integration become more reasonable and expedient. At the same time, this first approach implies that a mixed methods research synthesis has to remain sensitive to the positions in the primary-level studies, and to the position taken in the mixed methods research synthesis itself.
2. The second approach is that the positions do not have to be muddled if the separation and articulation of the positions is paramount. The mixed methods research synthesis can give dominance to a certain position (with other positions being auxiliary) or can work in sequences (Heyvaert et al., 2011, 2013b; Johnson and Onwuegbuzie, 2004).
3. The third approach comprises a philosophical third way out of the realist-idealist duality by embracing pragmatism (Biesta, 2010; Cersosimo, 2019; Feilzer, 2010). In pragmatism, as a philosophical tradition going back to the writings of Peirce (1878), James (1907), and Dewey (1925), knowledge about the world is defined by our actions. In this tradition, the meaning of statements and hypotheses have to be clarified by tracing their practical consequences – their implications for experience in specific situations (Legg and Hookway, 2020). In this way, pragmatism bypasses the contentious issues of the exact nature of reality and knowledge, and puts an emphasis on the consequences of our actions, possibly but not

necessarily based on our knowledge and world views (Feilzer, 2010). Pragmatism considers knowledge as a tool for prediction, action, and problem-solving rather than something that aims to merely describe, represent, or mirror one or multiple realities (Cersosimo, 2019).

4. The fourth approach refers to the research team that is conducting the mixed methods research synthesis (Curry and Nunez-Smith, 2015; Shulha and Wilson, 2003; O'Cathain et al., 2008). This team can be as diverse as the research problem requires, including statisticians, qualitative methodologists, and substantive experts. Such a research team can capitalize on the complementary background and skills of the team members, but perhaps more importantly, such a research team can prepare a thorough integration by engaging in a dialog about the purpose of the mixed methods research synthesis, the research question it proposes to answer, and the material that can be included. The in-between position of the first approach or the pragmatism in the third approach may offer a common language and make this dialog possible. On the one hand, this dialog assumes sensitivity and respect for the different positions and perspectives of the team members, and on the other hand, it can prevent the mixed methods research synthesis of degenerating in a clumped hodgepodge.

One or more of the previous four approaches can be used to position oneself as a systematic reviewer conducting a mixed methods research synthesis. A step-by-step guide for conducting the mixed methods research synthesis itself is presented and illustrated in the next sections.

A step-by-step guide for mixed methods research synthesis

The actual procedure for conducting a mixed methods research can be described in six discrete steps, which are similar to the step-wise approach of an empirical study: (1) writing a protocol and selecting a design, (2) selecting a sampling strategy, a search strategy, and eligibility criteria, (3) critically appraising the primary-level studies, (4) extracting the data, (5) analyzing and synthesizing the data, and (6) writing the report. In an ideal scenario, these steps are followed sequentially, but in practice there can be overlap or back and forth between steps. In this section, we focus on the essence of each step. For more details, the reader is referred to Heyvaert et al. (2017).

Writing a protocol and selecting a design

This protocol documents all methodological and substantive choices that are needed throughout the mixed methods research synthesis process. The protocol contains the selected mixed methods research synthesis design and a description of the choices made for the next steps. General guidelines for writing such a protocol can be found in Shamseer et al. (2015).

With respect to the designs, a basic distinction can be made between a segregated design, an integrated design, and a contingent design (Sandelowski et al., 2006). In a segregated mixed methods research synthesis design, the qualitative meta-synthesis and the quantitative meta-analysis are conducted separately and independently, and only afterward an attempt is made to synthesize both strands of evidence. In an integrated mixed methods research synthesis design, qualitative and quantitative studies are directly combined, for example by transforming the qualitative data into quantitative data and/or by transforming the quantitative data into qualitative data. In a contingent mixed methods research synthesis design, qualitative meta-synthesis methods and quantitative meta-analysis methods are used in cycles until saturation is reached and a comprehensive research synthesis can be presented that addresses the review objectives.

An example of a mixed methods research synthesis using a segregated design can be found in Heyvaert et al. (2014, 2015), who performed a systematic review of restraint interventions for challenging behavior among persons with intellectual disabilities. In the quantitative strand, they focused on the effectiveness of the interventions and in the qualitative strand, they focused on the experiences of the persons with intellectual disabilities, bringing the two strands together in the discussion section. Examples of mixed methods research syntheses using a contingent design can be found in Noyes et al. (2019), who presented three case studies of guidelines developed by the World Health Organization, which incorporated quantitative and qualitative evidence in sequential and iterative cycles. These guidelines only became established after the research team reached consensus based on the available quantitative and qualitative evidence. An example of an integrated mixed methods research synthesis design is presented in **Mixed methods research synthesis in educational research: an example** section.

Selecting a sampling strategy, a search strategy, and eligibility criteria

The sampling strategy may be exhaustive, selective, or purposeful, depending on the review objectives and the available resources (Booth, 2006). The search strategy stipulates which bibliographic databases, gray literature databases, journals, reference lists, and citation indexes are consulted, and which key words were used to perform the search. It may also involve contacting experts and authors for unpublished data. The eligibility criteria refer to the inclusion and exclusion criteria that are needed to filter out irrelevant studies and to retain only the primary-level studies that are relevant for answering the review questions.

Critically appraising the primary-level studies

Critical appraisal refers to the assessment of the methodological quality of the included primary-level studies. Because these studies can be quantitative, qualitative, or mixed, the critical appraisal is performed best for each of the evidence strands separately and should take into account that mixed methods studies are more than just the sum of their individual qualitative and quantitative strands of evidence, and thus require specific criteria (Heyvaert et al., 2013a). Furthermore, a decision is needed about a way to deal with the differences in methodological quality between the studies. Finally, because critical appraisal is heavily based on expert judgment, differences between the members of the review team should be identified and discussed.

Extracting the data

Data collection in a mixed methods research synthesis consists of extracting the relevant data from the included primary-level studies (Cooper, 2010). These data include (1) formal characteristics of each study, such as the authors, the publication date, and the publication source, (2) methodological characteristics of each study, such as a description of the participants, the design, and the instruments, and (3) substantial characteristics that are related to the research questions and the theoretical framework of the mixed methods research synthesis, such as the type of intervention that is studied, the main results, and the conclusions drawn in the primary-level studies.

It is recommended that a preliminary data extraction form and a coding guide are developed and that the extraction form and the coding guide are piloted for a couple of primary-level studies before extracting the data from the complete set. Also in this step, identifying and discussing differences in extraction between the members of the review team is mandatory.

Analyzing and synthesizing the data

Data analysis follows the logic of the selected design in the first step (Heyvaert et al., 2017). In a segregated mixed methods research synthesis, the quantitative studies (and the quantitative part of the mixed methods studies) are summarized using meta-analytical tools and the qualitative studies (and the qualitative part of the mixed methods studies) are synthesized using formal grounded theory, meta-ethnography, thematic synthesis, or meta-aggregative synthesis. Both strands of evidence are brought together by discussing how they complement each other and whether the potentially complementary findings can be arranged into a line of argument, into a theory that posits relationships among concepts, or into a narrative that posits a temporal ordering of events (Sandelowski et al., 2006).

In an integrated mixed methods research synthesis, techniques can be used for “qualitizing” the quantitative findings and for “quantitizing” the qualitative findings. For example, percentages addressed in questionnaires may be translated into textual data (e.g., “the majority of the participants”, “some participants”, “only a limited number of participants agreed on a particular topic”) to facilitate the creation of a narrative storyline or qualitative data, or the verbal counts in a qualitative study may be converted into numbers (e.g., the frequency of a particular finding, category, or theme). Moreover, three mixed synthesis approaches can be used for directly integrating qualitative, quantitative, and mixed primary-level studies: narrative summary (Borman and Grigg, 2009), critical interpretive synthesis (Dixon-Woods et al., 2006a; Dixon-Woods et al., 2006b), and realist synthesis (Pawson, 2002, 2006).

A contingent mixed methods synthesis may involve consecutive qualitative and quantitative synthesis approaches. However, it is also possible that within one, some, or all of the strands, a qualitizing, quantitizing, or mixed synthesis approach is used. An alternative approach is sequential Bayesian synthesis to draw on both qualitative and quantitative evidence. In such a sequential Bayesian synthesis, findings from the qualitative studies are used for eliciting prior probabilities for each of the research hypotheses included in the mixed methods research synthesis. Thereafter the findings from the quantitative studies on the same topic are used to update these prior probabilities, yielding posterior probabilities for each of the research hypotheses. If “quantitizing” and “qualitizing” techniques are added to this approach, then several sequences and cycles of updates are possible (see e.g., Crandell et al., 2011; Roberts et al., 2002; Voils et al., 2009).

Writing the report

Writing and disseminating the mixed methods research synthesis report is the final step in the process. If the synthesis report is intended for organizations promoting and supporting literature reviews, such as The Campbell Collaboration or The Cochrane Collaboration, then it is recommended to use their standard templates (Heyvaert et al., 2017). Additionally, templates have been developed for reporting on specific data synthesis approaches, such as the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA; Moher et al., 2009), ENhancing Transparency in REporting the synthesis of Qualitative research (ENTREQ; Tong et al., 2012), the RAMESES publication standards for realist syntheses (Wong et al., 2013), and the Joanna Briggs Institute’s standards for reporting on meta-aggregative syntheses (Lockwood et al., 2015).

Table 1 Number of mixed methods research synthesis articles indexed in the web of science for each publication year.

Year	07	08	09	10	11	12	13	14	15	16	17	18	19	20
Number	2	1	2	4	6	13	18	23	30	45	47	82	92	149

Note. Search was conducted on September 28, 2021. The search string was TS = ("mixed methods research synthesis") OR TS = ("mixed methods systematic review") OR TS = ("mixed method systematic review") OR TS = ("mixed methods synthesis") OR TS = ("mixed method synthesis") OR TS = ("mixed research synthesis") OR TS = ("mixed studies review") OR TS = ("mixed study review"). Topic Searches (TS) include title, abstract, author keywords, and Keywords Plus. Timespan: All years. Indexes: SCI-EXPANDED, SSCI, A&HCI, CPCI-S, CPCI-SSH, BKCI-S, BKCI-SSH, ESCI, CCR-EXPANDED, IC.

Mixed methods research synthesis in educational research

In order to explore the use of mixed methods research synthesis –as defined and discussed in the previous sections– in international peer reviewed journal articles, and in articles devoted to educational research in particular, we conducted a Web of Science search for the terms “mixed methods research synthesis”, “mixed method research synthesis”, “mixed methods systematic review”, “mixed method systematic review”, “mixed methods synthesis”, “mixed method synthesis”, “mixed research synthesis”, “mixed studies review”, and “mixed study review”, without any publication date restriction. We found a total of 514 unique articles, with the earliest publication date being 2007. The number of articles in each publication year from 2007 until 2020 is shown in **Table 1**.

Two results in **Table 1** are striking. First, mixed methods research syntheses, identified as such or with similar terms, do not appear in the scientific literature before 2007. Given that the advocacy of [Harden and Thomas \(2005\)](#) and [Sandelowski et al. \(2006\)](#) stemmed from a few years before, this result is understandable. Although it does not necessarily imply that (precursors of) mixed methods research syntheses are absent from the pre-2007 literature, it gives some indication that pre-2007 research syntheses did not bother to refer to the issues that are involved in mixing methods. Second, we see a steep increase in the number of articles between 2007 and 2020 referring to mixed methods research synthesis, with an increase of more than 60% from 2019 to 2020. Obviously, the popularity of this approach is rising and a plateau is not in sight.

Table 2 shows the number of articles referring to mixed methods research synthesis for different science categories in the Web of Science. The most frequently indexed category is “Nursing” with 103 out of 514 records (20%). The acclaim of mixed methods research synthesis in nursing is not surprising because nursing involves many complex real-world problems that have both qualitative and quantitative features. Furthermore, some of the leading methodologists in the field (e.g., [Margarete Sandelowski](#)) are associated with schools of nursing. As can be seen in **Table 2**, most other categories also have a link with health, and a minority with social sciences and multidisciplinary fields. “Education, educational research” shares the 14th, 15th, and 16th position with “Gerontology” and “Psychology, multidisciplinary” and is mentioned in only 13 records (2.5%). Further down the list (not in the Table), we encounter “Education, scientific disciplines” with 6 mentions (1.2%), “Psychology, educational” with 4 mentions (0.8%), and “Education, special” with 1 mention (0.2%).

Table 2 Number and percentage of mixed methods research synthesis records for each of the web of science categories.

<i>Web of science categories</i>	<i>Records</i>	<i>% of 514</i>
Nursing	103	20.0
Public environmental occupational health	93	18.1
Medicine general internal	82	16.0
Health care sciences services	62	12.1
Health policy services	30	5.8
Psychiatry	24	4.7
Rehabilitation	23	4.5
Social sciences interdisciplinary	22	4.3
Oncology	17	3.3
Pediatrics	17	3.3
Multidisciplinary sciences	14	2.7
Social sciences biomedical	14	2.7
Education educational research	13	2.5
Gerontology	13	2.5
Psychology multidisciplinary	13	2.5
Psychology clinical	12	2.3
Clinical neurology	11	2.1
Nutrition dietetics	11	2.1
Obstetrics gynecology	11	2.1

Note. Only the 20 most prevalent categories are included in the table. Percentages do not sum to 100% because records can be listed in more than one category.

The 22 unique records (4.3%) that are in an educational category are included in [Mixed methods research synthesis in educational research](#) Appendix. This relatively small number of articles referring to mixed methods research synthesis in educational research suggests that this approach is not reaching its full potential in this research field. Evidently, education is different from nursing, but they share the complexity, the societal relevance, and the importance of both qualitative and quantitative features. Moreover, a closer look at [Mixed methods research synthesis in educational research](#) Appendix learns that most mixed methods research syntheses in educational research even have a connection with health, exemplified by the fact that 14 of those 22 articles were published in medical education journals (*BMC Medical Education*, *Health Education Journal*, *Journal of Education and Health Promotion*, *Medical Teacher*, *Nurse Education Today*, and *Sex Education: Sexuality, Society and Learning*), school health journals (*Journal of American College Health*, *School Mental Health*, *The Journal of School Health*), or in journals on disabilities (*Journal of Applied Research in Intellectual Disabilities* and *Research in Developmental Disabilities*). It is difficult to fully understand this difference in the prevalence of mixed methods research synthesis between health-related research and educational research. Possibly the evidence-based medicine movement is a crucial factor, with educational research being less focused on summarizing evidence about effectiveness and safety, which is most prominent in the systematic review and meta-analysis literature.

Mixed methods research synthesis in educational research: an example

In this final section, mixed methods research synthesis is illustrated with an example from educational research found in our search: a study on sense-making for beginning special educators ([Mathews et al., 2017](#)). The example demonstrates that mixed methods research synthesis does not only deal with effectiveness and safety questions in health-related research fields, but that it also can be harnessed for more descriptive research questions in educational research. In this example, we follow the six mixed methods research synthesis steps mentioned before.

Writing a protocol and selecting a design

[Mathews et al. \(2017\)](#) posited the following research questions: “As represented in the literature, which elements of schools as organizations –including stressors and supports– are most influential in beginning special educator’s sense-making process? How do these elements promote or hinder beginning special educator’s development of professional identity and their response to the unique complexities of their professional role?” (p. 26). These research questions contain causal language, but the literature study is mainly about perceptions of “influence”, “promotion”, and “hindrance”.

For their theoretical framework, [Mathews et al. \(2017\)](#) drew on institutional and sense-making theories. Institutional theory refers to a theory about the ways in which organizational structures, norms, practices, and patterns of social relationships are connected to the broader social and cultural environment. Sense-making theory is used to focus on individual processes through which the beginning special educators construct their own understanding of policies, norms, and cultural messages, and how they construct meaning regarding their role, responsibility, and identity as a special education teacher. With respect to design, the authors used an integrated mixed methods research synthesis design in which qualitative and quantitative studies were directly combined using their theoretical framework. Their framework enabled them to transform the quantitative data into qualitative data.

Selecting a sampling strategy, a search strategy, and eligibility criteria

Their sampling strategy was purposeful. They conducted an electronic search of EBSCO and PsycNet databases and did a hand search of two journals that featured prominently in the electronic search, *Teacher Education and Special Education* and *Exceptional Children*. Furthermore, they scrutinized the references of and the citations to every selected article. For the search strategy, they used key words such as “teacher induction”, “teacher mentoring”, “special educat*”, “special education teacher”, “novice”, and “begin*” in various combinations, and they limited their search to articles published from 2002 onwards because they wanted to capture the experience of beginning special educators since the United States “No Child Left Behind” act was implemented. Given their research questions and for practical purposes, they only included studies that (1) examined special education teachers as a distinct group in sampling and results, (2) addressed beginning special educators in the induction period or mentoring programs, (3) were conducted in primary or secondary education settings in the United States, and (4) were available in English in a peer-reviewed journal.

Critically appraising the primary-level studies

The selected articles were critically appraised by using a modified version of the Mixed Methods Appraisal Tool (MMAT; [Pluye and Hong, 2014](#)). A minimum score of 25% on the MMAT was set by the research team for inclusion. Based on this criterion, three of the 21 articles were excluded. Furthermore, the MMAT scores were also used in the analysis (see Step 5); claims made in studies with a MMAT score smaller than 75% always required the support of studies with a MMAT score larger than 75%. The MMAT scores were double-coded for 35% of articles and an inter-rater agreement of 96% was obtained.

Extracting the data

The coding guide consisted of codes for the quantitative data with respect to the stressors and supports, the role of the stressors and supports in the professional experiences of the beginning special educator, and the extent to which factors such as mentoring and professional support helped beginning special educators navigate those stressors. Quantitative coding was performed for *a priori* specified variables deduced from the literature on teacher attrition in special education. The inter-rater agreement for the codes of the quantitative data was 75%, but the research team came to a consensus on all codes after a careful deliberation. The codes for the qualitative data emerged inductively during the analysis. Those codes specified how the stressors and supports, identified by the quantitative data, shaped the professional identity of the beginning special educator. After discussion and refinement with the research team, three main themes and corresponding codes emerged: affirmation, interruption, and identity construction. "Affirmation" referred to experiences that confirmed what was expected or anticipated, "interruption" referred to experiences that differed from what was expected or anticipated, and "identity construction" referred to experiences that defined, clarified, or potentially shaped the beginning special educator's professional role, responsibilities, and position within the organization.

Analyzing and synthesizing the data

A total of 9 quantitative, 8 qualitative, and 1 mixed methods study were analyzed and synthesized. All quantitative studies were surveys. The qualitative studies contained interviews, observations, journals or written reflections, questionnaires, teacher evaluation documents, and mentoring time charts. The mixed methods study combined interviews, observations, and a survey. During the analysis, the authors looked for emerging themes, relationships among those themes, and disconfirming evidence. They refrained from an actuarial approach and grouped the emerging themes with a focus on examining the influence of institutional elements on beginning special educator's sense-making.

Writing the report

For writing their report, Mathews et al. (2017) did not use a specific template, but rather presented their findings in a regular journal article format. In doing so, they used their theoretical framework to organize their report, present the results, and discuss the implications. The main findings from their mixed methods research synthesis were that (1) beginning special educators needed support to access resources and understand local school norms and culture, (2) rising student needs were associated with rising needs for support on the part of the beginning student educator, (3) school climate, including acceptance of students with disabilities and collective responsibility for student needs, is associated with a perception of relationships as collaborative, (4) principal leadership was instrumental in establishing school norms that supported a climate accepting of students with disabilities and in clarifying the role of special education teachers, and (5) the professional identities and roles of the beginning special educators were highly subjective and shaped less by fixed, regulated structures and more by local, dynamic interpretations of school regulations, school norms, and school culture.

Conclusion

Mixed methods research synthesis has become a versatile and popular method to systematically review research literature consisting of both qualitative and quantitative evidence for complex real-world phenomena. After initial methodological proposals and a few scarce applications in the first decade of this century, the number of published mixed methods research syntheses has risen to about 150 in the year 2020 alone and is expected to even surpass this yearly number in the years to come. This growing popularity is supported by the publication of step-by-step user's guides, such as in the handbook by Heyvaert et al. (2017) and a number of instructive journal articles that outlined the method, such as the articles by Heyvaert et al. (2013b), Pluye and Hong (2014), and Sandelowski et al. (2012).

This popularity is not a historical accident. As was argued in this article, mixed methods research synthesis is the method of choice for a systematic review if the research problem of interest is complex, consists of multiple components and layers, and if quantitative, qualitative, and mixed method studies have to be combined to tackle the research problem. Because systematic reviewing is more and more applied to complex research problems with important societal relevance and because qualitative, quantitative, and mixed method studies about similar phenomena are increasingly available and valued, it is expected that a mixed methods approach to research synthesis would be on the rise.

Surprisingly, however, in our exploration of the research literature, we only found 22 mixed methods research syntheses in the field of educational research out of a total of 514 applications in all fields between 2007 and 2020. This small number is surprising because educational research commonly has to deal with complex research problems that have huge societal relevance and because often qualitative, quantitative, and mixed method studies should be brought to bear to find a balanced, convincing, and sustainable solution. In this sense, educational research would be an ideal breeding ground for applications and methodological advances in mixed methods research synthesis.

With this article in the fourth edition of the *International Encyclopedia of Education*, we hope to have planted the seed for countering the underrepresentation of educational research in the mixed methods research synthesis literature. In this article, we have introduced this new method of systematic reviewing to a new generation of educational researchers, together with the benefits and pitfalls, with an accessible step-by-step summary, and with a worked-out example from educational research. After planting this seed, we hope that in the fifth edition a more rosy **Table 2** for educational research can be presented.

Introduction

A mixed methods approach to survey work in the education sector can yield benefits when it comes to instrument design (i.e., item writing, item placement, developing directions, a scoring scheme, and so on) and when conducting a full survey project. For purposes of this chapter, we define a survey project as a survey endeavor that includes all facets of survey work, including research question conceptualization, instrument design, framing a sample, drawing a sample, performing analyses, interpreting findings within the survey context, reporting, and dissemination of findings. This chapter describes general survey concepts and discusses how mixed methods are being used in a survey project we (the chapter authors) are currently leading called the *National Summer Learning and Enrichment Study* (NSLES). Discussion of mixed methods used in the NSLES offers readers an example meant to help describe some of the cost-benefit decisions researchers make when engaged in survey work with a mixed methods approach, particularly with respect to a projects' timeline and budget. To provide our conclusions up front, we see value in mixed methods survey designs, particularly one design where qualitative inquiry allows one to understand the research context in detail, prior to writing a survey instrument and delivering it. However, this design can be time consuming, so we opted for a mixed methods approach that allows for near simultaneous use of qualitative and quantitative inquiry, which was desirable because our example entailed a fast turnaround study.

Mixed methods survey research

Survey research is generally seen as a quantitative approach wherein an instrument is used to gather information from a large group of people. Much of survey item writing entails reducing respondent opinions to a numerically coded responses, and many survey sampling efforts will seek a sample that is statistically representative of some population of interest. Response samples are typically assessed for nonresponse bias, and statistical weighting and data imputation are often used to build confidence in results (see for e.g., Enders, 2010). These quantitative design approaches and statistical techniques yield data collection efficiencies and allow researchers to assess the validity of their findings.

Quantitative survey findings can respond broadly to critical research questions (e.g., for the NSLES: *What kinds of summer programming did school districts launch in 2021?*) and can provide insight into if, and how, the phenomenon in question varies across respondent characteristics (e.g., *Did districts with prior experience in summer programming provide a broader range of offerings than those that were launching summer programming for the first time?*). But if limited to quantitative methods, findings from surveys may lack sufficient detail and depth to fully explain what is happening, why, and under what conditions. This is because people are complicated (think about the different contexts in which people live, think, and behave) and their views are not easily boiled down to neat numerical scales and categorical choices. Because of these complexities, strictly quantitatively-oriented survey projects are vulnerable to multiple sources of error (reviewed below) that have the potential to threaten the validity of findings (see Dillman et al., 2014).

Mixed methods thinking can help limit these concerns. This type of thinking is an "orientation toward social inquiry that actively invites us to participate in dialog about multiple ways of seeing and hearing, multiple ways of making sense of the social world, and multiple standpoints on what is important and to be valued and cherished" (Greene, 2008, p. 20). Survey researchers who exercise mixed methods thinking hold the strengths and limitations of survey instruments front-and-center as they conceptualize how an instrument is designed, administered, analyzed, and how they report what they learn from it. They consider if and how integrating

qualitative inquiry within a survey (or via complementary tools) can add detail and depth to findings that stretch beyond what quantitative scales can obtain alone. By introducing qualitative inquiry into their work, researchers can find additional ways of capturing respondents' inherently multi-dimensional and nuanced opinions and life experiences, enable a deeper understanding of context, and mitigate survey error.

Mixed methods surveys and understanding individual respondents

When responding to a survey, individuals bring their prior assumptions about a topic (both explicit and tacit), their perceptions of themselves, their emotions related to specific topics, and their reasoning to the assignment. This can be true even if dealing with highly specific and technical matters. If, for example, a survey queries about staffing educational programs, it is likely respondents will have views informed by their prior school experiences. If a survey includes questions about how schools allocate limited funding, again most respondents will likely have underlying tacit assumptions that will influence how they respond. Tacit assumptions are personal opinions and ideas that may guide respondent behavior without their full awareness or, perhaps, without thorough self-examination (LeCompte, 2000). In addition to thinking about respondent assumptions, it might help to conceptualize respondent behavior; that is, how one interacts with a survey. Survey behavior can include whether one chooses to respond to the survey in whole, ignore some items, remain engaged during the response process (e.g., reading questions carefully and thinking through answers as opposed to offering rote responses to several items just to get through the experience), and so on. Tying these concepts together, if survey researchers are to expect reasonably high response rates, and thoughtful and honest responses (i.e., desirable survey behavior), it is critical to have some sense of the tacit assumptions respondents will likely carry.

Another challenge in survey work is that it can be difficult for a survey researcher to know what to even query in a survey, or to have confidence that a set of items adequately cover a topic because human beings are complex. After all, people are intersectional; that is, they exist within dynamic social contexts that shape their identities (American Psychological Association [APA], 2017). It is also important for survey researchers to develop a sense of the context in which the survey project will be conducted. A mix of quantitative and qualitative information can help account for contextual variation, which informs and influences individuals, the ways in which they experience and perceive the world, and how they might respond to a survey.

Using ecological systems theory to conceptualize a survey project

Bronfenbrenner's (1979) ecological systems theory (EST) provides a basis for thinking about context at different levels, its dynamic nature, and how it is co-constructed by people who live and operate within it. Furthermore EST, summarized in Table 1, can be used by researchers when making methodological decisions (Onwuegbuzie et al., 2013), particularly when considering how to blend quantitative and qualitative items in a way that informs findings and helps audiences consider the impact of programs and practices on individuals across a range of situational influences.

For example, this chapter was written in the midst of a recent and significant contextual shift: the global COVID-19 pandemic and this strongly influenced the NSLES. During this time, schools abruptly closed their doors, students began remote learning at

Table 1 Summary of Bronfenbrenner's ecological systems theory, focusing on system levels.

<i>System level</i>	<i>Description as applied to education research</i>
Microsystem	The level at which survey respondents interact with and influence their immediate environment; this represents context a person can co-construct (e.g., a student influencing the classroom context).
Mesosystem	This is the level wherein microsystems interact (e.g., a student's parents and teachers working together entails interaction between classroom and family microsystems).
Exosystem	There are typically multiple exosystems that influence microsystems but are not directly influenced by research participants (e.g., the school or district a student attends).
Macrosystem	This level represents broader cultural and societal factors (how a society values the teaching profession, funds schools, etc.).
Chronosystem	This level refers to time and changes brought on by development and life events.

scale and with little to no preparation, schools then began to reopen, and state and district educational agencies received federal stimulus funds to, among other things, accelerate student learning to make up for lost time. In addition to educational issues, health and safety issues, have and continue to weigh heavily on people's minds, but there is also controversy about matters such as vaccine mandates and whether children should wear masks in schools. Such context will influence how people respond to most surveys pertaining to education topics. The survey we are working on addresses urgent questions related to how educators are responding to this challenge within the United States, and we assume respondents will be influenced by their views around how schools should operate during the COVID-19 pandemic.

A key point here is that although a survey must be designed to inform research questions, it should also account for context, intersectionality, tacit assumptions, and individual differences throughout its construction and/or with complementary methodology (e.g., interviews). Mixed methods research can accomplish such survey design by blending quantitative inquiry with a qualitative mindset throughout different stages of a survey project is emblematic of [Greene's \(2007\)](#) "mixed methods way of thinking" (p. 20). Survey researchers with both quantitative *and* qualitative information can have a more holistic understanding of research questions.

Approaches to using mixed methods in education survey research

Qualitative data collection can be integrated within a survey instrument or can be accomplished through supporting tools within a larger survey project. For example, there is an option to obtain narrative responses via survey items, or a researcher can ask respondents to provide representative documents (e.g., written summer programming plans), both of which might be subject to qualitative analyses. In addition, survey efforts could be supplemented with qualitative phases (e.g., interviews, focus groups, document analyses) and it is possible for a project to be weighted toward qualitative work. At a more fundamental level, survey data can be seen as having both quantitative *and* qualitative features ([Sandelowski et al., 2009](#)). This is because responding to Likert-type items can be seen as a way to quantize a respondent's opinion and, conversely, one could qualitize a numerical response by asking a respondent to elaborate in a follow-up interview ([Onwuegbuzie and Leech, 2021](#)). Hence, survey work (as in instrument design and when conducting a full survey project) can be highly aligned with mixed methods thinking and design. An implication of this view of mixed methods survey work is researchers can use both qualitative and quantitative inquiry in flexible ways to conduct a survey project.

Understanding mixed methods survey research using the NSLES example

This chapter describes how mixed methods survey ideas can be pursued by describing how the authors applied them to a current survey project being carried out at a national level, within the United States. This chapter does not present survey findings; indeed, these findings are arguably irrelevant to our purpose in writing this chapter. Rather, we present mixed methods design thinking that went into conceptualizing our project so that readers might consider these matters when they engage in their own mixed methods survey design work. Some, but not all of the mixed methods ideas presented in this chapter have been used in the actual survey effort, and we describe how we arrived at a range of these methodological decisions. For example, due to the time-sensitivity of the topic and a strong appetite for rapid feedback for the education sector, we had to conceptualize and field our survey within a matter of weeks. Yet several techniques described in the remainder of this chapter take up time and resources that were not consistent with this study's demands. We therefore direct the reader to published studies that used survey techniques that we did not use in our survey project. Readers will need to perform their own cost-benefit analyses for their own survey projects. In our project, we are confident in our decisions to not use some mixed methods techniques because we think that we have a good grasp of the survey context at hand. Through this presentation, we hope to clarify the kinds to cost-benefit analyses that are familiar to many social scientists.

Introducing the context of our survey project

Fig. 1 presents our use of EST to understand the survey context. This figure uses EST levels from **Table 1** and provides a visual depiction of how these systems interrelate in the context our national survey project, which focused on understanding school-district summer programming. The broadest EST level is the macrosystem, and we conceptualize this as US macro-culture, federal policy, and national response to the pandemic. Within the macrosystem are exosystems, which we conceptualized as school-districts and the community a district served. Within a given exosystem, we conceptualized mesosystems that capture the interaction between summer programming and other district and community initiatives. We conceptualized specific summer programs as microsystems. Finally, EST reminded us to consider the chronosystem, or change over time. The implication of the figure is it provided us with guidance around item writing (e.g., we asked about micro-level summer program characteristics, and how they were informed by mesosystem-level community partnerships) and interpreting responses within the macrosystem and across time.

The survey project the chapter co-authors are leading is designed to promote an understanding of the types of summer programming school districts offer in 2021. There are several challenges and opportunities surrounding this project. To begin, at the exosystem and chronosystem levels, the United States is as of this writing struggling with social and economic consequences of the COVID-19 pandemic. Schools have experienced long periods of unplanned, emergency remote instruction and there remains

Fig. 1 Applying EST to understand the context of a survey project.

deep concern that interruptions to normal learning processes will reap long-term developmental challenges for the nation's children, especially among more vulnerable groups. Consider for example that the New York Times (a prominent newspaper in the country) worked with Stanford University to analyze kindergarten enrollment data from 33 states, covering 10,000 schools. The analyses showed a 20% enrollment drop among these children; furthermore, this drop in enrollment increased by 28% in communities close to or below the poverty line (Goldstein and Parlapiano, 2021). The implication of these enrollment declines is that tens of thousands of students began the first grade in 2021 without the benefit of a year in kindergarten.

Long-term consequences from this event are to be expected. Of course, one might wonder if some on-line instruction at least ameliorated the problem; however, Engzell et al. (2021) offer some troubling insights. These researchers evaluated the effect of school closures on primary school children's academic performance in The Netherlands by exploiting the fact that national examinations were conducted shortly before and after an 8-week lockdown was initiated to combat virus spread. Engzell et al. compared the academic progress of these children across these eight weeks to three prior cohorts for which there are testing data during the same point in the school year. The main finding is that learning loss for the cohort that experienced the pandemic induced school closure was equivalent to about one-fifth of a school year (or about eight weeks, the length of the school closure time). In contrast, prior cohorts demonstrated growth in student performance during their respective timeframe during the school year. In short, the study found that emergency remote instruction was not effective. It seems reasonable to assume this form of instruction was also not

effective in other countries. It is for example widely documented that in March of 2020 the United States abruptly engaged in “shut-downs” and school buildings were closed quickly enough that teachers had almost no time to plan for needed instructional changes. This event was problematic enough for all students and their families, but whereas some households could at least afford things like broad-band Internet access and tutoring, others did not. Empirically speaking, [Lewis et al. \(2021\)](#) found that in the United States, students in Grades 3–8 demonstrated learning gains in 2020–2021 but not as much compared to learning typically observed in pre-pandemic trends. Furthermore, students in minority groups performed lower than their majority-group peers, and students attending high-poverty schools performed worse than students attending schools in communities with more resources.

One macrosystem level approach toward addressing widespread learning disruption in the United States is the *American Rescue Plan Act (ARP)*, which is part of a major financial stimulus package that among other goals supported schooling. Among the various provisions in the plan, states were given in March of 2021 funding to begin new forms of summer enrichment and learning programming. ARP support should continue through 2024. It is hoped that summer programming and other out-of-school time enrichment experiences will serve to ameliorate the pandemic-related learning disruptions, especially among more vulnerable children. This provides critical context for the survey project presented in this chapter that is informed in part by mixed methods thinking.

It should not be surprising that we think it a challenge to understand the summer programming offerings delivered across a diverse nation and how to generate findings that school district personnel might use. There is a summer learning evidence base (e.g., [McCombs et al., 2021](#); [Peterson and Vandell, 2021](#); [Schwartz et al., 2018](#)) but plans and strategies have been changing at an extraordinary pace to address this ever-evolving pandemic context. One key challenge is timing, and the authors of this chapter are leading a survey effort to understand the summer programming offered by school districts just months after passage of the ARP. The effort entails obtaining a nationally representative sample of districts and presenting findings in time to help inform decisions for Summer 2022, which creates the sense of urgency underlying this project that in turn shortened the project timeframe. The project, the NSLES, is also a mixed methods endeavor because parallel efforts are underway to analyze state and district documents that describe summer programming. Furthermore, the project is carrying out an extensive set of interviews that will contextualize and extend survey findings.

Mixed methods design decisions applied to NSLES

The remainder of this chapter is structured by (a) summarizing widely used and longstanding ideas in survey design and instrument development coupled with formally mixing in qualitative design elements to yield a mixed methods survey project and (b) describing how these ideas were and were not applied to the NSLES. Survey projects, and the context in which a survey is delivered can begin to be understood by thinking through four sources of survey error ([Dillman et al., 2014](#)), and the degree to which such error will invalidate findings. These sources of error are summarized in [Table 2](#).

As noted in [Table 2](#), the four sources of error include coverage, measurement, nonresponse, and sampling error.

Table 2 Sources of survey error.

Source of error	Description
Coverage	Researchers develop a sampling frame from which to draw a sample. The degree to which a given frame does not adequately cover (i.e., capture) the target population of interest yields a form of error. For example, the NSLES target population is all U.S. public school districts. ^a The degree to which the sampling frame NSLES used does not cover all U.S. school districts is the degree to which the researchers assume there is error undermining estimates observed from a randomly drawn sample. Fortunately, NSLES was able to use the National Assessment of Education Progress school district frame, which is maintained by the National Center of Education Statistics housed in the U.S. Department of Education, ^b meaning that the sampling frame has excellent coverage, so this form of error does not represent a serious threat to the validity of the study findings.
Sampling	This form of error is dictated by sample size; it deals with precision, or the width of a confidence interval around a sample estimate that should be described because observations are based on sample statistics and not population parameters. Sampling error decreases as sample sizes increase. NSLES drew a random sample of 550 districts. Dillman et al. (2014) offer a sampling formula (p. 56) for anyone wishing to calculate precision estimates. Suffice it to say for this chapter that a 60% response rate will yield adequate sample sizes assuming a 5% confidence level.
Measurement	This form of error deals with psychometric properties and the degree to which survey items properly cover the constructs of interest. NSLES needed to field an instrument approximately six months after passage of the ARP and no time was available for prior qualitative inquiry and pilot testing (details below). The survey was developed with the aid of a technical working group (TWG) with considerable content expertise. The implications of NSLES timing for mixed methods survey design are reviewed at several points in this chapter. Broadly speaking, prior qualitative inquiry can help item writers be aware of and try to account for matters of context, respondent intersectionality, and tacit assumptions that will influence survey behavior.
Nonresponse	Survey findings are undermined when randomly sampled participants do not respond. Statistical techniques such as nonresponse weighting and data imputation can mitigate this form of error. Strong contextual knowledge can however promote response rates; mixed methods implications are described later in this chapter.

^aThere are approximately 13,452 school districts in the United States ([National Center for Education Statistics, 2020, n.d.](#)).

^bSee: <https://nces.ed.gov/nationsreportcard/>.

Coverage error deals with the degree to which a sampling frame from which a sample is drawn matches up to the actual population of interest. These frames are critical when researchers plan to draw random samples as a basis for arguing that a sample is representative of a target population. In the NSLES, we specified all 13,000+ US public school districts as the target population and drew a stratified random sample of 550 of these districts from the National Assessment of Education Progress data frame. There are however instances where a researcher might opt for purposive sampling (Patton, 2015). By purposive sampling, we mean taking a non-random approach toward identifying respondents (Patton, 2015). Researchers might adopt one of approximately 40 different purposive sampling strategies such as criterion-based sampling (e.g., ensuring the selected sample meets some pre-specific criterion like district size in terms of number of students served), or maximum variation sampling (e.g., ensuring a sample of districts varies in size). Purposive sampling can be useful when an adequate sampling frame is not available, the population of interest is quite small (e.g., when conducting a case study in a school and one surveys teachers), or when the survey focus is not on statistical representation but instead exploring and describing phenomena (e.g., barriers teachers experienced when implementing a new teaching technique in a school). Furthermore, surveys sometimes are used in some qualitative investigations such as ethnographies (e.g., Schensul et al., 1999) and are not necessarily predicated on statistical generalization. In such studies precision estimation is rendered moot although it is still worthwhile to think through the degree to which survey findings generalize within the study context (Onwuegbuzie and Johnson, 2004). In terms of the NSLES, statistical generalization is a goal, so coverage error is evaluated in Table 2.

Sampling error connects to mixed methods survey design thinking because it deals with quantitatively-oriented considerations around sample size and precision of sample estimates. This is however primarily a quantitative concern, so this chapter does not offer detail; readers instead only need to understand that (a) there is an inverse relationship between sample size and sampling error (i.e., sampling error decreases as samples get larger) and (b) even though sampling error decreases as sample size increases, there is a point of diminishing returns such that very large sample sizes (n of 500 or more) are often not needed for reasonable precision (Dillman et al., 2014).

Mixed methods researchers have interconnected measurement error, psychometrics, and qualitative inquiry when it comes to instrument development (see for e.g., Creswell and Plano Clark, 2017; David, 2022; David et al., 2018; Newman et al., 2013; Onwuegbuzie et al., 2010). A fundamental connection between psychometrics and mixed methods can be understood via the social exchange framework, and the aforementioned EST. Social exchange, a concept from the survey literature, posits that the likelihood a person will respond to a survey is informed by the cognitive demand of the instrument and the perceived social benefit of responding to it (Blau, 1964; Dillman et al., 2014). And, germane to this chapter, we suggest that perceived social benefit can be seen as a tacit assumption. In terms of an exchange, as the perceived value of the work increases, so will the effort respondents put into providing survey answers. This means questions need to be interesting and reflect the values of the target population, and it must be evident that the results of the survey will yield a positive social impact if surveyors wish to see respondents persevere through a long list of items or take seriously items that are challenging (as in cognitively challenging, emotionally taxing, or both). Conversely, if a survey entails just a few simple items, then response rates might be high even in absence of a perceived positive social benefit because the effort to respond will be minimal.

Applying EST can help the surveyor think more completely about the survey context

Considering the microsystem level, one might be cognizant about items querying about respondents' capacity to influence an environment, or just as well, any lack of agency they might experience. Again, items need to be interesting and perceived to be of value, and querying people about what they can and cannot do is usually a good start to compelling item writing. The microsystem context also informs a potential respondent's decision to begin a survey and answer all items (i.e., survey behavior), which gets into the matter of nonresponse error. Understanding the lives of target respondents can inform decisions about providing incentives to respond and positioning a survey request that honors respondents' circumstances. The NSLES for example is surveying district superintendents and their delegates. Awareness of the superintendent role as it typically plays out in the United States and how US schools do not always accept emailed survey links means that the NSLES team put considerable resources into multimodal forms of outreach and multimodal ways for respondents to send back data. Personalized letters announcing the survey with descriptions of how study findings might inform Summer 2022 planning, coupled with offering respondents the opportunity to communicate by phone, Email, paper mail, and weblinks are all built into the system because of the broad understanding of superintendent's daily lives. The meso-system level helps surveyors be cognizant that (a) summer programming generally entails community partnerships and (b) interactions of staff occur at all levels of a district. To the first point, considerable attention was put into writing items about district partnering; to the second point, the survey was designed to be shareable in the event a superintendent does not know some given detail about summer programming. Finally, at the exosystem level, one needs to think about the context of a district's capacity to participate in research from both a policy level and at a technology level. For example, from a policy perspective, the NSLES randomly sampled some districts with formal Institutional Review Boards that require the survey team to apply for a response request. An example of being aware of technology context is the team understands that some districts have strict rules around whether emails with hyperlinks can pass through firewalls and there are any number of security and data privacy considerations that can undermine response rates. Awareness of these concerns highlight the importance of context.

Having made these points, the NSLES was able to field a survey without relying on specific mixed methods techniques. Recall from Fig. 1 that the macro context at hand is the NSLES was funded after the Spring 2021 passage of the ARP to study how this federal act influenced Summer 2021 programming. This means the survey had to be conceptualized, written, and tested all in a matter of weeks while also drawing a random sample of districts. More development time could be taken on the back end,

but social exchange in this case is largely predicated on the message that survey responses will be analyzed and disseminated in time to help inform future summer programming. NSLES does however have some unusual assets that made project leaders comfortable in foregoing several mixed methods development techniques. The first is the contracting organization fielding the survey, Westat, has staff with hard won contextual knowledge around district-level surveying, having just completed other survey projects that entailed asking questions of superintendents. A second asset is the project is supported by a panel of experts with considerable summer learning and educational leadership content knowledge and research methodology knowledge. This panel will inform mixed methods analyses that NSLES will pursue (described later in this chapter).

We list several techniques that ideally would have been used in NSLES instrument development had there been more time, representing a trade-off referenced at the outset of this chapter. See [Table 3](#). The techniques in this table include conducting pre-survey interviews, focus groups, and document analyses to learn more about the research context prior to instrument design, developing a Table of Specifications, using Delphi methods, cognitive interviews, pilots and psychometric analyses. Note that citations for follow-up study by interested readers are offered in the table.

Use of any or all of these methods assumes there is not already a survey that is adequate for addressing a set of research questions at hand. Furthermore, use of these techniques assumes researchers enter survey development with a strong command of relevant literatures and therefore understand prior survey efforts, constructs of interest, and how constructs interrelate with each other.

Mixed methods survey design options

Fortunately, there are established mixed methods research designs that can simplify the use of techniques described in [Table 3](#). One such design is the *Exploratory Sequential Design* (see for e.g., [Creswell and Plano Clark, 2017](#)). Creswell & Plano Clark refer to this design as one of their prototypical designs, meaning they can be altered for different purposes. [Fig. 2](#) provides a basic application of this design to survey work.

The figure shows that qualitative data collection and analyses are performed at the outset of the survey project. This can be a highly effective way to understand contextual concerns at all levels captured by EST, likely tacit assumptions held by potential respondents, and some sense of their intersectionality. Furthermore, strong qualitative inquiry can go a long way toward informing research questions to be addressed by a survey, identifying specific populations of interest, considerations in sampling approaches, messaging about a survey, developing survey directions, how to write items, optimal ways to group items within an instrument, survey length respondents will tolerate, and effective ways to disseminate findings. In short, we cannot think of any part of a survey project that would not benefit from prior qualitative inquiry. As mentioned above, this is true even when performing statistical procedures for purposes of psychometrics, missing data imputation, and non-response bias and weighting analyses. This is because statistical decisions and interpretation of analyses can all be better informed by the type of insights typically won from prior qualitative work. We wish we could have applied an exploratory sequential design to NSLES. The fact that we did not apply this design points to the key challenge that [Creswell and Plano Clark \(2017\)](#) recognized; the design does entail considerable time to implement in part because of the potential to develop a new instrument. The NSLES team recognized that several prior qualitatively oriented project phases could not be executed in the available time, so the exploratory sequential design was not used. We do hope that if we are able to pursue future survey work then time will be available to take full advantage to this powerful approach to surveying.

Another prototypical sequential option that could be deployed is the *Explanatory Sequential Design*, also described by [Creswell and Plano Clark \(2017\)](#). See also [Ivankova et al. \(2006\)](#) for an extensive discussion and insights about this design; [Gesser-Edelsburg et al. \(2020\)](#) offer an example of how it has been used. The basic design is depicted in [Fig. 3](#).

The explanatory sequential design can be used in a survey project if the researchers conduct follow-up qualitative inquiry with survey responders to gain more in-depth understanding of phenomena and potentially refine the survey if it will be used again. One could for example purposefully sample respondents who were outliers, as well as respondents who offered more typical survey responses, and ask them questions around why they responded the way that they did, if they have more to say about the phenomena of interest, and so on. This provides clear advantages, but as with the exploratory sequential design, [Creswell and Plano Clark \(2017\)](#) note that it will generally take a relatively long time to deploy.

Incidentally, if time pressures are not a serious concern, then a variant of multiphase sequencing can yield a powerful form of mixed methods inquiry used to address survey-instrument development. Imagine being able to start a research project with a qualitative phase, then a quantitative one, followed up by yet more qualitative inquiry and continuing the process until research objectives are met. The [David et al. \(2018\)](#) study referenced in [Table 3](#) was able to use a multiphase design (interviews were conducted to inform item writing, a pilot sample produced responses subject to item response theory analyses, more interviews were conducted to work out item refinement, psychometric analyses were again conducted). If this sounds like a lengthy process, it was. Like most research endeavors, time (and budget for funded work) needs to be carefully considered whenever sequencing is deployed.

One mixed methods design that can be more time efficient is the *Convergent Parallel Design*. In this approach, the qualitative and quantitative research strands are mostly independent, and findings are mixed during analyses. See [Fig. 4](#).

The NSLES used this approach; the qualitative strand entails document analyses of state level plans to use ARP funding to support summer programming, analyses of district websites that describe summer programming, and interviews with state and district officials. The quantitative strand is the survey of a nationally representative sample of school districts. A key justification for using this design is it minimizes the weaknesses inherent in each component approach. NSLES stakeholders want a statistically representative sample of districts to describe Summer 2021 programming; this will provide a unique set of findings in that we will

Table 3 Mixed methods survey development techniques.

<i>Technique</i>	<i>Description</i>
Pre-survey stakeholder exploratory interviews and/or focus groups	NSLES did not use this approach because of time limitations but if an additional month or two of development time were available the study team would have interviewed a few superintendents experienced with summer program delivery. There are varied approaches for how to conduct interviews and numerous considerations for how extensive this effort should be. Interviews can be exceedingly valuable for better understanding phenomena of interest and how to write survey items that properly cover constructs to be covered by a survey. Our own personal experiences lead us to believe that informal interviewing is quite common, even among survey researchers who are not especially familiar with qualitative or mixed methods research (our position is that if interviews are used, there is merit in taking full advantage of quantitative inquiry to generate item writing). On the other end of the continuum, sometimes extensive interviewing is needed to inform item writing, such as when dealing with abstract constructs (David et al., 2018 for example develop a measure of trust, which is an idea that is hard to concretize in a survey). Hitchcock et al. (2005) conducted extensive interviews prior to item writing to account for cultural factors; a key need because the survey was fielded in Sri Lanka.
Document analyses	NSLES was able to engage in brief document reviews by examining available state ARP plans that described summer programming (full qualitative analyses were not completed until after the survey was fielded); the project director also had prior knowledge of best practice guidance around summer programming. Documents can be thought of as any physical or written artifact (e.g., scientific reports, newspaper articles, marketing materials, websites, video, audio recordings, personal diaries; see Patton, 2015) that will help researchers understand target phenomena. Analyses generally entail developing a coding protocol that is designed to extract relevant data for a multitude of coding options (see for e.g., Saldaña, 2021).
Mixed methods Table of Specifications (TOS)	The NSLES did not develop a formal TOS because of time limitations but did vet survey items with its expert panel. A TOS is a tool or checklist used to help researchers be sure that the totality of items adequately covers (measures) the phenomena of interest. Newman et al. (2013) developed a mixed methods TOS procedure using techniques like audit trails, expert debriefing, and peer reviews to develop transparent assessments of content validity.
Delphi methods	These methods generally entail multiple rounds of surveying or interviewing stakeholders/experts about some phenomena of interest to obtain feedback or make predictions. Usually, anonymity is afforded in the process because after a first round of feedback participants can see the judgments of others to refine their thinking. Anonymity allows for later changes in opinion without letting others know who changed their mind, and influence is won through force of argument and not the name or position of the person advancing an idea. There are several Delphi Method variants (Patton, 2018); when applied to survey development they can be used to brainstorm items or sometimes judge existing items for purposes of refinement (e.g., Tapio et al., 2011). In the context of NSLES, a Delphi study with the expert panel would have been an excellent exercise, if time allowed.
Cognitive interviews	This process is sometimes referred to think-aloud protocols or cognitive labs. There are different approaches; a common technique is to ask a proxy survey respondent to take a survey and react to it verbally to help researchers identify if there are confusing wording in directions or items, identify mismatches between item stems and response options, and so on. Willis (2005) authored a book on using interviews to improve survey design. NSLES would have ideally conducted cognitive interviews with school superintendents.
Piloting	The benefits of piloting should be obvious. If time allows, identify 30 or so proxy sample members and ask them to take the survey and provide feedback on any and all aspects of the tool. Johanson and Brooks (2010) found that a sample of about 30 participants will be adequate for obtaining Cronbach alpha estimates, which can be used to assess internal consistency of any scales and if any items reduce the size of these estimates (which would mean they might be problematic and should be deleted or rewritten). Hitchcock et al. (2015) provides other examples that demonstrate the benefits of piloting. The NSLES would have used piloting to refine the survey if not for time constraints.
Mixed methods psychometrics	Methods for assessing reliability and various forms of validity can be facilitated by relying on qualitative techniques and mixing them into psychometric work. David et al. (2018) for example conducted a series of focus groups to understand how to write items about trust, piloted an initial survey, assessed item fit using item response theory analyses, and conducted follow-up interviews to refine items that were determined to be problematic. This process was used across multiple iterations until the survey was finalized. Hitchcock et al. (2005) demonstrate how to combine exploratory factor analysis and qualitative thematic analysis as part of a mixed methods construct validation exercise. NSLES will over time be able to conduct some of these analyses after descriptive findings are made available to the public.

Fig. 2 The basic exploratory sequential design applied to survey work.

Fig. 3 The basic explanatory sequential design applied to survey work.

Fig. 4 The NSLES convergent parallel design.

be able to generalize results to a national level and understand how federal investment was deployed to combat mass learning disruptions in primary and secondary schooling. But of course, surveys are not designed for highly in-depth and exploratory inquiry. Hence, the interviews and document analyses of a smaller purposive sample will provide us with more in-depth understanding.

Data analyses and interpretation

Given the variety in design options there is no one way to pursue analyses in mixed methods survey projects. Three broad pieces of advice are: (a) to follow best practices in component analyses (i.e., quantitative analyses and qualitative analyses), (b) be sure to account for all data sources during analyses, and (c) find optimal ways to mix information when interpreting findings. In the case of NSLES, our survey analyses largely will be descriptive in nature because this fits the nature of the research questions (e.g., what percent of school districts in the United States offered summer programming in 2021? What percent of districts plan to offer summer programming in 2022?). The analyses will however entail some exploratory prediction modeling. When conducting analyses of survey data best practices are to evaluate and account for nonresponse bias, perform outlier analyses (i.e., the accuracy of and understand any extreme responses noted in the sample) and clearly describe the degree of precision through presenting confidence intervals when deriving sample estimates. Any prediction modeling will account for modeling assumptions and our audience will be informed of project limitations and threats to the validity of findings pertaining to our understanding of Summer 2021 programming in the United States.

As of this writing all qualitative data collection is pending. Our qualitative coding generally will follow [Saldaña's \(2016\)](#) straightforward process of (a) identifying all available raw data (interview data, document data), (b) collating datum points into codes, (c) categorizing codes, (d) developing themes and concepts from the codes, and (d) generating findings and assertions. Coding procedures will be vetted with our expert panel. Since we will adopt an exploratory position, we will reserve the right to revisit analyses through different forms of second-cycle coding. To explain, Saldaña identified multiple styles of coding wherein analysts can focus on identifying, for example, data patterns, change over time (longitudinal coding; respondents might describe programming

Table 4 Summary of credibility techniques to be applied to NSLES.

<i>Credibility technique</i>	<i>Description</i>
Member checks	We will ask some interview respondents to check the accuracy of our interpretations and conclusions. Did we capture their intended meaning? Member checks can also support document analyses. We will consider the question with some respondents: did we capture and correctly interpret key details about summer programming?
Triangulation	This entails searching for and interpreting consistency across different data sources (i.e., survey, documents, interviews), as well as any inconsistency (e.g., if a survey respondent claims a district offered little summer programming but interviewees describe robust programs, then we need to address the inconsistency to develop credible findings).
Negative case analyses	These analyses entail a purposeful search for discrepant evidence to challenge and test initial assumptions and findings.
Peer debriefing	We will leverage our expert panel to review findings and provide critical feedback.
Audit trail	We will keep records of all research activities (data collection, dates for key decisions, document choices to not pursue some line of inquiry but identify it as being worthy of future study) to substantiate claims about findings.

prior to the ARP, Summer 2021 programming, and future plans), and coding that helps us develop a theory that summarizes how district and state personnel think about summer programming as an intervention for addressing disruption in student learning.

Following best practices, we will deploy different credibility techniques (see for e.g., [Brantlinger et al., 2005](#); [Nastasi and Schensul, 2005](#); [Patton, 2015](#)) including member checks, triangulation, negative case analyses, and so on. The techniques the NSLES will use are summarized in [Table 4](#).

Note that [Table 4](#) does not list all credibility techniques used in qualitative and mixed methods research; it instead highlights key approaches we plan to use in NSLES as a part of our intended qualitative analyses.

Our mixed analyses will at a minimum rely on joint display of findings and profile analyses. A joint display is an analytic tool (i.e., developing a joint display is an analytic process) that presents both quantitative data (for NSLES, survey findings) and qualitative data (NSLES themes and assertions) to allow for direct comparison, merging, and mixed triangulation (see for e.g., [Creswell and Plano Clark, 2017](#); [Fetters, 2020](#); [Guetterman et al., 2015](#); [Haynes-Brown and Fetters, 2021](#)). We cannot as of this writing provide a visual example of our planned joint display because data have yet to be collected and we will adopt an exploratory analytic approach, so we do not yet know what story we will tell. [Haynes-Brown and Fetters \(2021\)](#) however offer straightforward guidance on joint display development. In summary, Haynes-Brown & Fetters would counsel us to consider: (a) how the joint display supports our analyses as we compare, contrast, and merge findings from different data sources, (b) ways to present a complex array in a user-friendly manner so that we can describe findings, (c) incorporate theory and understanding of context to explain our interpretations, and (d) select the most descriptive of available text data.

Profile analyses ([Tashakkori and Teddlie, 1998](#)) will exploit the fact that we will purposefully select some districts that responded to our survey and meet maximum variation criteria pertaining to Summer 2021 offerings. Specifically for purposes of profile analyses, we will purposefully select districts that:

- (a) offered extensive programming and there is evidence the district has advanced experienced with summer learning;
- (b) offered typical forms of summer programming and the district is not a particular outlier in the dataset in terms of experience; and
- (c) offered minimal programming and has a history of doing so.

We will analyze select districts in these profiles and compare and contrast their Summer 2021 circumstances to identify lessons learned from advanced programming, and to understand barriers to programming. We hope our analyses will yield insights as to how these barriers might be addressed in future summers with the support of ARP funds.

The combined use of joint displays and profile analyses that are supported by high quality component analyses should position us to generate defensible findings and varied forms of user-friendly reports. At this point it helps to revisit the idea that mixed methods survey work can and should take full advantage of contextual knowledge to inform report dissemination as one way to honor social exchange. We plan to disseminate information as fast as possible through venues supported by the U.S. Department

of Education and websites visited by school superintendents in the United States (e.g., the School Superintendent Association) and topically aligned venues such as the National Summer Learning Association. NSLES procedures and findings will eventually be presented in peer-reviewed journal outlets, but we know our context and audience as a function of the project being led by a person with deep content expertise and an expert panel that understands the summer learning and enrichment field. This knowledge compels us to present findings with rapidity and widely to promote the greatest possible reach of this work. Other mixed methods survey projects might have the benefit of more time at the outset of an endeavor and/or after inquiry is completed but might also not have access to a broad swath of experts who enter a project with a strong understanding of context. In these cases, adopting an exploratory sequential design will almost certainly lead to a successful project because this design allows researchers to better understand the research context through initial qualitative inquiry.

Conclusion

A key take home point from this chapter is mixed methods thinking can interweave through all stages of a survey project, from initial conceptualization, formulation of research questions, specifying a target population and sampling frame, sampling decisions, survey design and item writing, analyses and interpretation, reporting and, finally dissemination. Importantly, variants of the advice and ideas presented in this chapter can be found in survey resources provided by major publishers and have informed the field across multiple book editions (e.g., Dillman et al., 2014; Fowler, 2013; Groves et al., 2009). However, key contributions of a mixed methods way of thinking come from taking full advantage of formal qualitative inquiry and mixed analysis approaches that can help one generate instruments and understand findings from quantitative, qualitative, and mixed lenses. We have emphasized the importance of using qualitative inquiry to understand the context in which a survey will be fielded and to help account for respondent intersectionality, people's tacit assumptions, and context that in turn will influence survey behavior. In the example we provided, the NSLES, initial qualitative inquiry was not possible because of time limitations, which is something to consider whenever thinking about a design with sequenced phases. Although NSLES is supported by staff with deep content expertise who are embedded in national summer learning ecosystems, and operational staff who have repeatedly surveyed school districts for national projects, we still would have adopted an exploratory sequential design had time allowed. Doing so would have given us the chance to interview stakeholders and documents before item writing and we could have further deployed techniques described in Table 3 of this chapter.

Despite this limitation of not being able to use mixed methods procedures for survey-instrument design, the NSLES will take advantage of mixed methods procedures using qualitative data strands (i.e., document/website analyses and interviews). *The key take-home point to appreciate here is a mixed methods survey project can exploit disparate methods to minimize weaknesses in component design approaches.* Surveys can be delivered to large sample sizes and utilize sampling technology to help researchers have some assurance that findings are generalizable to a target population. This might be especially important for large-scale endeavors such as mobilizing national efforts to address a pandemic-related learning disruption. It is also true, however, that at least compared to qualitative inquiry, surveys are weak with respect toward deeply exploring topics. It is hard to imagine how even the most sophisticated of surveys will include all needed items, written in an optimal way. Interviews and document analyses will offer much better chances to explore phenomena. But of course, the weakness of these approaches is they are intensive and time consuming. We cannot interview staff from all randomly sampled districts in time to offer the kind of information we think the field will need to inform Summer 2022 programming. Hence, although the NSLES is an imperfect example of a mixed methods survey project, readers will hopefully see the power that mixed methods can bring to inquiry through this concept of minimizing weaknesses of component designs. This weakness minimization is not addressed just by collecting different forms of data, the notion of mixing is crucial during analyses. In the case of NSLES, the combination of joint displays and profile analyses will create in-depth insights and elaborations around parameter estimates that should generalize to all public-school districts in the United States. Hence, even though mixed methods surveys can be time consuming, they need not be under the right circumstances and hopefully readers of this chapter will be inspired to deploy some of the design ideas described here when they pursue their own survey work.

Introduction

This discussion of mixed methods research to inform culturally tailored interventions is situated within several developments in education and psychology: *Conceptually* within an ecological systems approach to program development and evaluation; *methodologically* within implementation science, evidence-based practice, and translational research; *socially-cultural-politically* within efforts to address cultural diversity in science and practice. Addressing cultural diversity is especially critical to development of interventions within the international realm, given the limitations of current research evidence based predominantly on populations from North America and Western Europe (Arnett, 2008). Moreover, the limitations of current evidence have implications for addressing diverse cultural needs within domestic contexts (e.g., US communities). Mixed methods hold promise for understanding the role of “culture and context when one attempts to influence, or assess, the behavior, thought processes, and perceptions of others” (Nastasi and Hitchcock, 2016, p. 2, italics in original). In this chapter, we (a) explore the conceptual, methodological, and social-cultural-political foundations for culturally tailored interventions; (b) examine the role of mixed methods in development and evaluation of culturally tailored interventions, using a participatory approach; (c) provide examples from international literature; and (d) conclude with implications for educational research and practice.

Foundations

Conceptual

Bronfenbrenner’s (1998, 1999) ecological systems theory (EST) provides a framework for addressing *culture* and *context* in development and evaluation of culturally tailored interventions. Briefly, culture refers to “a dynamic system of meanings, knowledge and actions that provides actors collectively, interpersonally, and individually with community-legitimized strategies to construct, reflect upon, and reconstruct their world and experience, and guide behavior” (Nastasi et al., 2015, p. 96).

Context, or the *microsystem* within EST, refers to the immediate setting in which experiences occur (e.g., classroom, playground). The microsystem is embedded in a larger *exosystem* (e.g., the school), which is embedded within a social-cultural-political-economic system, referred to as the *macrosystem* (e.g., the larger community/society). Understanding or influencing experiences within a given microsystem (e.g., classroom) also necessitates consideration of other microsystems relevant to the individuals (peer group, family, neighborhood, etc.). In addition, the experiences of the teacher and other students within the classroom are relevant to understanding classroom dynamics. The interaction of the components of the ecosystem (micro-, exo-, macro-) and across ecosystems (e.g., school, family) is referred to as the *mesosystem*. Moreover, functioning in the immediate context is influenced by past experiences (i.e., the *chronosystem*). Finally, the interactions within an ecosystem are dynamic, such that the individuals within a microsystem are active agents and influence the system.

Applying EST to intervention research and development requires a mixed methods formative inquiry step to explore the influential contextual and cultural factors within the ecology. For example, to facilitate school connectedness, the researchers must first examine the perspectives of all key stakeholders (students, teachers, school administrators, other school staff, parents/caregivers) about relationships, feelings of safety and danger, conditions or interactions which facilitate or inhibit healthy interactions. This inquiry should include data relevant to culture, by gathering from all stakeholders, the values, beliefs, norms, and language related to key constructs. In addition, researchers would need to explore school and district policies that govern teacher-student and student-student interactions, such as policies related to discipline practices, bullying, social-emotional learning, peer relationships, etc. Data can be gathered using observations, interviews, focus groups, survey instruments, secondary data, and records review. Finally, researchers would need to examine points of conflict or agreement across stakeholder groups or context related to positive school relationships and safety. These data could then guide planning of interventions to facilitate school connectedness.

The EST can guide examination of the immediate context and factors that influence interactions in that environment. This understanding is essential to development and evaluation of interventions, especially those that attempt to address culture and context (i.e., are culturally tailored). The complexity of EST necessitates research and evaluation methodology that can account for experiences of individuals, influential cultural and contextual factors, and the dynamic nature of human and systemic interactions. In this chapter, we explore the role of mixed methods in development and evaluation of interventions embedded within ecosystems, in this case specific to educational settings (classrooms, schools, community).

Methodological

The impetus for considering the complexity of intervention development and evaluation is the recognition of the limitations of existing approaches that rely on research conducted in highly controlled settings (e.g., randomized controlled trials, RCTs), often without consideration of multiple factors within the immediate context and larger ecosystem. These limitations became apparent as practitioners attempted to implement RCTs and met challenges in adapting the interventions to contextual and cultural variations. Recognition of the limitations of RCTs led to developments known as evidence-based practice, implementation science, and translational research.

The call for *evidence-based practice (EBP)* came from psychology (APA, 2006) and medicine (Institute of Medicine, 2001). Briefly, EBPs require the integration of existing intervention research, the expertise and experience of the implementer (e.g., clinician, teacher), and consideration of culture and context (see Nastasi and Hitchcock, 2016, for further discussion).

Implementation science (IS) extended the study of interventions within highly controlled settings in recognition of the importance of contextual and cultural factors on implementation of evidence-based interventions by researchers and interventionists from multiple disciplines (psychology, education, medicine, public health). IS requires the study of myriad factors that influence development and evaluation of interventions and can inform evidence-based practice (Eccles and Mittman, 2006; Fixsen et al., 2005; Moullin et al., 2019).

Similar to implementation science, *translational research* is concerned with the implementation of evidence-based interventions in natural settings, and requires the study of factors that influence acceptability, integrity, ecological validity, adaptation, and effectiveness as practitioners attempt to apply interventions supported by existing research. Translational research thus involves the examination of intervention implementation *in vivo*, as practitioners attempt to implement and adapt evidence-based interventions and requires ecological or systems thinking and participatory approaches (Silver et al., 2021; Scarpa and Trickett, 2022).

EST provides a conceptual framework for engaging in EPB, implementation science, and translational research. That is, the study of the ecosystem in which an intervention occurs can lead to the identification and monitoring of influential contextual and cultural factors, and thus help to facilitate effective interventions in natural settings. Quantitative and qualitative methods and their integration through mixed methods research (MMR) are necessary to capture the complexity of the ecosystem to inform development of culturally tailored interventions (Nastasi and Hitchcock, 2016). For example, the formative inquiry related to school connectedness described above might yield data about student perceptions of teachers' discipline procedures as increasing levels of stress and inhibiting coping, thus leading to more aggressive behaviors toward peers. Furthermore, teachers might indicate that the school's discipline policies inhibit developing caring relationships with students and preclude efforts to foster student coping with strong emotions. Data may also reveal high levels of bullying with minimal adult intervention, and lack of opportunities to develop better peer relationships. Data may also reveal inequity related to punishment of students based on race and gender, with black males most likely to receive severe punishment. Further data collection might reveal perceptions of black male students as more aggressive, despite observational data to the contrary. These findings suggest need to address racial and cultural beliefs, to develop better understanding of how to interpret behavior within a diverse population, and to institute efforts to foster better teacher-student relationship with all students. Bell and colleagues (Bell et al., 2017) provide an example (detailed in a later section) of using formative MMR data to develop a culturally and contextually tailored intervention in one school.

Social-cultural-political

Coinciding with calls for better understanding of implementation of science in natural settings was social-political recognition of the importance of addressing diversity within the population at global, national, and local levels. Recognition of the limitations of science based on Western cultures of North America and Western Europe with populations that were predominantly White, middle class, well educated, and represented only 5% of the world's population (Arnett, 2008), led to calls for research and practice that account for diversity and recognition of the need for culturally specific or culturally tailored interventions. Of course, developing such interventions requires first the understanding of the specific culture of the target group within their ecology, and subsequently the monitoring of cultural and contextual factors that can influence effectiveness. Qualitative research methods are ideally suited for in-depth study of culture and context (Nastasi and Hitchcock, 2016). Combined with quantitative methods, researchers can further track changes and outcomes of interventions. In this chapter, we examine the potential role of MMR for engaging in translational research, thereby addressing limitations of existing intervention research and facilitating culturally tailored evidence-based practice.

Culturally tailored interventions

The integration of ecological systems theory, implementation science, and cultural diversity, for the purpose of developing culturally tailored interventions, requires complex mixed methods research designs. *Culturally tailored interventions*¹ refer to interventions that are designed to address the needs of specific cultural group(s) embedded within cultural context(s); for example, designing or adapting an intervention to the needs of a marginalized group (e.g., low-income African American students) within a specific school context (e.g., elementary school in urban neighborhood). *Tailoring* the intervention requires understanding of the experiences of the students within their ecology (e.g., classroom within school located within community and larger society). Understanding the ecology necessitates exploration of cultural norms, values, beliefs, and practices of the classroom and larger school context through observation, interviewing and examination of cultural artifacts. Thus, before the tailoring can occur interventionists must first study the culture of the target population within the target ecology, that is, beginning with study of the ecological system from perspective of stakeholders.

The study of culture is depicted as the second phase (learning the culture) in the *Participatory Culture Specific* (cf. *Culturally Tailored*) *Intervention Model* (PCSIM; Fig. 1; Nastasi et al., 2004). The PCSIM extends a more traditional approach to intervention research by including in-depth research that leads to design, adaptation, and evaluation of an intervention tailored to the cultural group and context. The tailoring is achieved through use of mixed methods research to inform the development of the intervention. Furthermore, the process requires engaging key stakeholders as partners in the research process.

As depicted in Fig. 1, PCSIM begins with examining existing theory, research, practice, and policy (Phase 1); followed by formative MMR to learn the culture and context (Phase 2) and forming partnerships with stakeholders (Phase 3). Once the goal or problem is identified (Phase 4), researchers in partnership with stakeholders conduct formative MMR (Phase 5) to gather data about key constructs of interest (e.g., student mental health, peer relationships) and to identify influential factors (e.g., stressors and supports, cultural differences among peers, lack of school mental health programming). A critical component of Phase 5 is understanding the key constructs and influential factors from a cultural and contextual perspective, through gathering perspectives of stakeholders and studying the ecology. The data collection leads to development of a local model or theory (Phase 6) that will guide program design (Phase 7) and adaptation (Phase 8; e.g., culturally tailored version of existing program). The local theory/model will

Fig. 1 Participatory Culture Specific (cf. culturally tailored) Intervention Model (PCSIM)

The 10-phase model for development of culturally tailored interventions reflects a dynamic and recursive process of mixed methods research, conducted in partnership with key stakeholders, to inform program design, implementation, and evaluation. The goal of PCSIM is culturally and contextually tailored interventions that are acceptable, socially valid, and sustainable. The *light blue* boxes depict the phases of traditional program development; the *dark blue* boxes indicate the additional phases within PCSIM. From Nastasi, Moore, Varjas (2004, p. 54). Copyright 2004 by the American Psychological Association. Adapted with permission. The use of APA information does not imply endorsement by APA.

¹Also referred to as culturally specific, culturally relevant, culturally sensitive, culturally appropriate (Nastasi et al., 2015).

likely reflect existing theory, research, practice and policy, but be tailored to the local culture and context. MMR data collection continues throughout program implementation to facilitate monitoring, further adaptation, and assessing impact; and at program conclusion to examine outcomes (Phase 9). The final phase (10) is focused on ensuring that the system has capacity to continue program efforts and to engage in the process of program development (capacity building), and on translation of the program to other contexts. Although Phase 10 explicitly addresses capacity building, the researchers with stakeholders will likely focus on building capacity throughout the PCSIM process.

Traditional program design is reflected in the light blue phases (1, 4, 7, 9) in the model. Thus, typically interventionists examine existing theory, research, practice, policy (Phase 1) to identify evidence-based interventions (EBIs) often endorsed by a policy body as validated for use in school settings, for the purpose of addressing the identified goal or problem (Phase 4). The interventionists then design, implement, and evaluate the intervention (Phases 7 & 9) based on the identified EBI, often in a standardized or manualized fashion. The chosen EBI may or may not have been validated for the target population and context, and thus is not necessarily culturally tailored. The addition of the dark blue phases (2, 3, 5, 6, 10) facilitates the development, evaluation, and translation of culturally tailored interventions.

One might conceptualize PCSIM as a participatory mixed methods action research process. In the subsequent sections, we examine the use of mixed methods with PCSIM and discuss the role of participation to facilitate an action research process.

Using mixed methods in PCSIM

As depicted in Fig. 1, PCSIM is characterized by an iterative process of *research* $\leftarrow$ $\rightarrow$ *intervention* that occurs at specific phases and across the cycle from conceptualization to translation. Thus, research is intended to inform program design, monitor program implementation, facilitate program adaptation, and evaluate program impact. Nastasi et al. (2010) have characterized the research cycle depicted in Fig. 1 as a synergistic and fully integrated mixed methods design. That is, qualitative and quantitative methods are used in each phase of the cycle, with outcomes of each phase reflecting the mixing or integration of quantitative and qualitative findings. So, for example, researchers might consider both qualitative and quantitative findings from existing research to inform their worldview and conduct mixed methods research to understand the cultural context (Phase 1 & 2). The study of culture and context (Phase 2) using qualitative and quantitative methods is especially critical in understanding the ecological system. For example, in the context of a school, this might involve participatory observations, interviews with key informants (e.g., administrators, lead teachers), focus groups with key stakeholder groups (e.g., teachers, parents, students), and examination of school record data and policies. From this process, one is prepared to form partnerships, identify system needs, and formulate goals (Phases 3 & 4). Mixed methods are again needed for conducting formative research (Phase 5) to fully understand the system needs and contributing factors. Researchers can engage in mixed methods inquiry using qualitative methods (e.g., participant observations, interviews, focus groups) and quantitative methods (e.g., surveys, school record data, community census data) to define key constructs (e.g., school success, student performance, psychological well-being) and identify contributing factors (e.g., school climate, economic factors, poverty, community violence, etc.). Consistent with an ecological approach, research would extend beyond the school to include, for example, community and national data to depict population needs and contributing factors. The integration of the MMR data can then inform development of a model for culturally tailored interventions relevant to the school population and ecosystem (Phase 6) that guides program design (Phase 7). Phase 7 can involve selection and adaption of evidence-based interventions or creation of new culturally and contextually relevant interventions. During implementation, researchers engage in formative evaluation using mixed methods to monitor program acceptability (e.g., for students, parents, teachers, administrators), social validity (cf. cultural fit), integrity (cf. fidelity), and short-term impact (Phases 8 & 9). This formative evaluation may lead to further program adaptation and system support (e.g., teacher coaching, team problem-solving, additional resources), and mixed methods can help to track implementation of adaptations and their impact on program success. Summative evaluation (Phase 9) addresses program outcomes following program completion, and can address impact on participants (e.g., students, teachers) and the system (e.g., changes in policies and procedures), as well as examine the links between process (e.g., implementation practices) and outcomes. Phase 10 addresses program sustainability and capacity building which are dependent the participation of key stakeholders as partners in the PCSIM process. Mixed methods can be used to assess factors relevant to sustainability and capacity, such as stakeholder commitment, resource allocation, infrastructure, staff competencies, and policies.

Facilitating participatory action research for capacity building

Development of culturally tailored interventions is likely to necessitate active participation of key stakeholders; for example, in the case of school interventions—administrators, teachers, parents, students, and perhaps community members. Achieving an in-depth understanding of culture requires capturing the voices and experiences of key stakeholders, and preferably their engagement as partners. Using participatory approaches such as participatory action research (PAR; Friedman and Antal, 2005; Greenwood et al., 1993; Maister et al., 2008), transformative mixed methods (e.g., Mertens, 2007), and PCSIM, researchers can effectively engage stakeholders as partners to create meaningful and sustainable change. Furthermore, capacity building is dependent not only on partnerships but also on facilitating professional development of staff and building necessary infrastructure that may require changes in school policy and procedures and acquisition of additional resources.

Mixed methods research can contribute to sustainable change by first incorporating sustainability as a goal, and secondly, using integrated qualitative and quantitative methods to examine system and stakeholder needs and resources, understand system

dynamics that influence decision making and change, represent voices of all stakeholders, and inform data-based decision making. So, for example, researchers might meet with partners (e.g., representatives from respective stakeholder groups) to discuss long-term goals for the system in the context of the current short-term intervention goals, and then engage in the PCSIM cycle of research $\leftarrow$ $\rightarrow$ intervention to design and implement capacity building plans. This might include training and/or hiring new staff, forming partnerships with community agencies, seeking support from government agencies, instituting new policies and practices, etc. To complete the cycle, MM would be used to evaluate implementation of plans for sustainability and capacity building.

What is necessary to facilitate PAR for systems change? First, identifying partners with vested interests and resources, and being inclusive in forming partnerships by inviting representatives of all groups that will be affected (e.g., students, parents, community members as well as school staff). Second, as part of the PCSIM process, ensuring that partners develop capacity to engage in a continual process of monitoring and change. Thus, the goal extends beyond implementing a culturally tailored intervention to include building system capacity to continue similar processes in the future. Third, facilitating collaborative problem-solving and decision-making among stakeholders; for example, through training of staff and other stakeholders, creating a team process, and promoting culture of collaboration in the organization. Finally, identifying and fostering stakeholder strengths to facilitate empowerment. Creating sustainable systems change requires that stakeholders have the capacity to continue the process of change as context and culture vary or evolve over time. In the next section, we examine examples of the transformative process through participatory MMR for development of culturally tailored interventions.

Examples of MMR for culturally tailored interventions

Examples of mixed methods research and development can be found in international literature. In this section we highlight research and development approaches using participatory MM, consistent with PCSIM, to develop culturally tailored interventions with populations both inside and outside of the United States. The studies summarized here represent school- and community-based work conducted in Botswana, Canada, Hong Kong, Sri Lanka, the US, Korea, and South Africa.

Chilisa and Tsheko (2014) used an indigenous mixed methods approach to develop sexual risk prevention programs for adolescents in Botswana. Program developers engaged in a process consistent with PCSIM, first using research to learn the culture and establish partnerships, then conducting formative and evaluative research using “indigenous mixed methods” (p. 223) as the basis for designing and evaluating interventions that were culturally tailored. A unique aspect was the use of indigenous mixed methods relevant to oral societies, described as “metaphorical sayings, stories, songs, and proverbs serve as the literature, words of wisdom, commentaries on events and behaviors, and socialization instruments for youth and adults” (p. 226). Research methods included qualitative, a combination of indigenous methods (stories, songs, proverbs, etc.) and semi-structured and structured interviews; and quantitative, a culturally tailored (indigenous) survey instrument to measure sexual attitudes, beliefs, and behaviors. The survey instrument was developed based on qualitative data. The initial data collection phase served as basis for designing and evaluating the indigenous intervention, which incorporated indigenous methods (e.g., talking circles), and was co-constructed with stakeholders. Central to research and development within this project were the partnership with community stakeholders, use of indigenous methods for communication and intervention, and inclusion of adolescent voices.

Bird-Naytowhow et al. (2017) describe a participatory community research partnership with Plains Cree and M’etis youth from one urban Canadian environment of Saskatoon, Saskatchewan. The project engaged youth, local elders, and community collaborators as partners in identification of sources of resilience that would inform program development for positive youth development. A basic assumption of the project was that “resources, knowledge, and capabilities required to support the health and wellness of Indigenous youth are already present within inner-city contexts and the young people themselves and thus need only to be collaboratively identified, learned about, and fostered” (p. 2). Youth were primary partners throughout the project. Adopting the view of research as a *ceremonies of relationship* process, researchers integrated photovoice and talking circles as context for interviews with youth. At the conclusion of the project, the youth developed a community exhibit and engaged in interviews with local media as ways to disseminate findings. This project illustrates how researchers can use Indigenous knowledge to facilitate meaningful research for a community. Drawing on local ways of knowing and communicating, researchers can build relationships with local stakeholders and identify culturally relevant (tailored) strategies for effecting social change. The authors described their approach as an example of *two-eyed way of seeing*, combining Indigenous and Western ways of knowing (cf. combining emic and etic perspectives), an approach that is applicable to conducting research with other non-Western populations.

Ling and Pang (2022) conducted a transformative MMR study with Grade 7 ethnic minority (non-Chinese) students from a Hong Kong secondary school. The goal of the study was “to improve the financial literacy of ethnic minority students through financial education, as a step toward ending intergenerational poverty” (p. 133). Researchers used a 3-phase transformative MMR design that included: Phase 1, MMR to facilitate relationship building and contextual analysis, which informed intervention design; Phase 2, intervention implementation with formative qualitative evaluation; and Phase 3, MMR summative/outcome evaluation. Data collection in Phase 1 consisted of surveys and semi-structured interviews; these data informed development of vignettes to be used in the intervention. Phase 2 data consisted of audio-recordings of lessons and written work for qualitative analyses. Phase 3 data were derived from qualitative and quantitative questions of post-evaluation survey. This study illustrates the use of student voices for informing development of educational curriculum, using vignettes based on real, hypothetical, and phenomenologically oriented stories to enhance financial education of ethnic minority early adolescents.

Nastasi and Jayasena (2014) engaged in a multi-year project in Sri Lanka to develop culturally tailored instruments and interventions for promoting psychological well-being of school-age children and adolescents. Using MM across the phases of PCSIM, the

researchers collaborated with 18 schools in Central Province of Sri Lanka to conduct formative ethnographic research (e.g., interviews and focus groups with students, teachers, and school administrators) that provided the basis for development of self-report measures of perceived competence and stress and coping, and development of a culturally tailored intervention program that was implemented and evaluated in one school. The intervention program was later modified to address long-term psychological well-being needs of students, parents and teachers living in the Southern Province who were affected by the 2014 tsunami. The Nastasi and Jayasena article also describes the levels of collaboration that included not only relationships with ministries of education and schools, but also the partnership of the two researchers.

Bell et al. (2017) used a participatory action research approach to develop universal mental health programming in an urban school in the Southern part of the US. The school's action research team (principal, teachers, parents, students, and organizational consultants) participated in decision making throughout the process of formative research, goal identification, and intervention design, implementation, and evaluation. Mixed methods used for formative and evaluative research purposes included focus groups, interviews, observations, and surveys. The integration of qualitative and quantitative data with interpretation by the school action research team informed program design, monitoring, and evaluation. This study illustrates the integration of stakeholder voices with MM data to inform system change.

Kim (2014) used a mixed methods action research approach to understand the context of poverty among Korean children, including relevant policy and values, and to develop, implement, and evaluate a community-based intervention to facilitate transformative life-long learning among students living in poverty. The research was participatory and included voices of elementary and secondary students, parents, instructors, administrators, and community members. The project involved three phases. In Phase 1, researchers conducted a contextual analysis, with qualitative methods to examine legislation related to eliminating generational poverty in Korean and history of local child community centers (CCCs), and quantitative analyses to examine demographics of children served by these centers. Phase 2 involved a 2-year case study of a local CCC; researchers conducted focus groups with adult (center staff, parents, community members) and child (elementary and middle school students) participants in CCC to examine their perspectives on the inhibiting and transformative factors related to perpetuation of inequality and social injustice. Focus group data contributed to development of adult and child surveys to confirm findings with a larger sample. The researchers then conducted a workshop with parents and CCC staff to interpret findings related to inhibiting and facilitating factors and to inform development of transformative programming for children. In Phase 3, mixed methods action research phase, researchers partnered with CCC staff and parents to develop, implement, and evaluate two transformative lifelong learning programs for children. The authors described the process as "community-involved, collaborative and [characterized by] communicative interactions among the participants" (p. 314). This study is an excellent example of a systematic approach to action research, using MMR and participation of key stakeholders throughout the process of program development and evaluation.

Bridwell-Mitchell (2012) used a two-stage sequential, mixed methods design (Qual→Quan) design to explore the role of macro-level societal institutional factors as influencers on teachers' reactions to school reform and their subsequent instructional decisions at the micro-level of classroom (cf. ecological systems theory, EST). Findings from their research, conducted in the north-eastern region of the United States, provided support for EST applied to education, particularly teacher practices. That is, teacher decisions about classroom practices, at the microsystem level, are influenced by both external societal (macrosystem) level factors and internal institutional (exosystem) level factors, necessitating the consideration of the ecological system when trying to understand how school reforms influence classroom practices.

Kapofu (2019) engaged in focused ethnography using mixed methods (observations, interviews with teachers, school artifacts of incidents/events) to understand classroom culture as interpreted by teachers within one school in South Africa. Using semi-structured interviews, the researcher explored teachers' cultural assumptions about pedagogy, power, relationships, and social identity, to understand teaching practices. The study highlighted the critical relationship of the teacher's cultural assumptions as they guide the teaching-learning environment.

These illustrations highlight the integration of MMR with a participatory process for the purposes of (a) understanding culture and context as a necessary step to facilitating culturally tailored interventions; (b) engaging stakeholders in intervention development and evaluation to ensure representation of their voices in decision making; (c) understanding key constructs and influential factors embedded in the cultural context; (d) creating and evaluating culturally tailored interventions; and (e) ensuring capacity building and sustainability. As illustrated in Fig. 1, a participatory action research process extends traditional practices related to selecting, implementing and evaluating evidence-based interventions (depicted in light blue) by incorporating MMR to facilitate learning the culture and forming partnerships; conducting formative research to inform culturally tailored intervention model; conducting evaluation research to facilitate implementation, adaptation, and effectiveness; and facilitate sustainability and capacity building (depicted in dark blue). Existing research, illustrated herein, demonstrates the feasibility and effectiveness of processes such as PCSIM.

Conclusion

Participatory MMR situated within an ecological systems approach holds promise for facilitating implementation science and translational research to address cultural diversity in science and practice. Engaging stakeholders as partners in the process of research and development can help to ensure cultural relevance, ownership, and sustainability. Using MM to study the target culture and context and key variables of interest can help to inform development of a culturally and contextually tailored intervention. Furthermore,

using MM and stakeholder participation in design, implementation and evaluation of interventions can help to facilitate ecological fit, acceptability, integrity, and effectiveness. Finally, MMR in collaboration with stakeholders can facilitate identification of the necessary policies, structures and processes for building capacity within the system to sustain culturally tailored interventions. As highlighted herein, processes such as PCSIM can be helpful not only for advancing implementation science and translational research but also for facilitating transformations in existing practices through the integration of MM with participatory approaches.

Introduction

The idea of mixed methods, that is integrating distinct qualities of data and different methods of analysis in one study (Creswell and Plano-Clark, 2018; Tashakkori et al., 2020), has been extensively discussed in the domain of educational research (Johnson and Onwuegbuzie, 2004). In this chapter, we will contextualize the idea of mixed methods within the field of social network analysis, a methodological and theoretical framework that highlights the role of social structures and relationships (Borgatti et al., 2009). In other words, we are intersecting the discussions about mixed methods and social network analysis to arrive at Mixed Methods Social Network Analysis (Froehlich and Brouwer, 2021; MMSNA; Froehlich et al., 2020c).

The chapter is structured as follows. First, we will define MMSNA and describe its two “components,” mixed methods and social network analysis. We then briefly discuss methodological advancements in social network analysis from a historical perspective to understand the necessity for MMSNA to study educational phenomena. We then review the current academic discourse around MMSNA. For that, we discuss recent systematic reviews and then zero in on a selection of topics that receive a lot of attention in current methodological texts about MMSNA. We end the chapter with a conclusion and outlook.

Defining mixed methods social network analysis

For rest of this chapter, it will be useful to have a clear understanding of the nature of what we call MMSNA. Therefore, we will now define this methodological approach. We first turn to the individual parts that make up MMSNA: social network analysis and mixed methods.

Social network analysis (Borgatti et al., 2009; Wasserman and Faust, 1994) describes an array of methods and associated theories (Fuhse, 2020) that put an emphasis on social relations and social structures (Wasserman and Faust, 1994). Conceptually, social network data is specific in that cases are (assumed to be) interdependent and at least two pieces of information should be available. First, information about the actors of a network, which are more technically referred to as nodes. Second, information about the relationships (ties) between these actors. These two pieces of information are then used to construct a new entity, the network, which then often becomes the central object of the study. The network is then, in its simplest form, composed of the actors (e.g., pupils, teachers, family members, etc.) connected through various types of relationships (e.g., friendship, collaboration, etc.). The visual representation of such a network may also be called a sociogram; a tabular presentation could be a relationship or adjacency matrix or an edgelist (see Fig. 1; Wasserman and Faust, 1994). In this chapter, we cannot focus more on the basics of social network analysis—which are, of course, a prerequisite to make sense of MMSNA—but other accessible sources exist for the interested reader (Längler et al., 2020; Mejeh, 2020; Scott, 2007).

Mixed methods research can be defined as “research in which the investigator collects and analyses data, integrates the findings and draws inferences using both qualitative and quantitative approaches or methods in a single study” (Tashakkori and Creswell, 2007, p. 4). While variations of this definition exist, for the scope of this chapter it is sufficient to focus on the integration of different

Fig. 1 Representations of a network.

natures of data or vastly different approaches of looking at the data to explore a phenomenon. We just noted “different natures of data” here and not the common qualitative/quantitative distinction, as some social network researchers argue against the usage of the terms “qualitative” and “quantitative” data in the context of social network analysis. This is because the main feature of network data is more about its structural or relational properties. Social network data not only contains information about cases’ attributes (like most statistical datasets that assume independence of cases), but also includes information about how cases are dependent on each other. Indeed, social network researchers often merge two datasets into one to perform network analysis; one describing a set of cases (often referred to as a “nodes table,” which is akin to a conventional statistical dataset) and the other describing the relationships (for instance in the form of an edgelist, which we will discuss below). Since academic training often emphasizes statistical methods, readers may wrongly assume statistical datasets when reading about quantitative data. Nevertheless, in order to improve the clarity of writing, we will refer to qualitative and quantitative methods as a shorthand for qualitative and quantitative structural or relational methods.

In the previous paragraphs, we have discussed SNA and mixed methods as individual elements of MMSNA. But how do the given definitions inform a definition of MMSNA itself? There have been especially two discussions in the literature that should be noted here. *MMSNA in the broadest sense* describes any research design that includes both definitions given above. Note that we interpret this to mean adding mixed methods-thinking to social network analysis, rather than the other way around. This means that not only different natures of data or analytical procedures are included, but that at least one element of the research design features a relational or structural component (Froehlich et al., 2020c). As a simple illustration, we might think of a mono-method quantitative network study, to which we add a qualitative pre-study to develop the measurement instrument (see Schoonenboom et al., 2018 for development as a purpose of mixing methods). This research design includes quantitative and qualitative data and methods and hence can be labeled a mixed methods research design. Also, it features social network analysis. Applying the broad definition of MMSNA, we could, therefore, call it a MMSNA research design.

In a narrower sense that we call mixing *within* social network analysis, we require the use of qualitative and quantitative relational/structural data and/or qualitative and quantitative methods of relational/structural analysis. The example from above would not meet this requirement, as the qualitative pre-study presumably is not about any relational phenomena. As an illustration of a MMSNA design in the stricter sense, we might think of a mono-method qualitative interview-study, in which we seek to explore the social relationships the interviewer is entangled in. Again, we now add another strand of research to further develop this qualitative strand of research: We add a quantitative strand of research to inform the selection of interview partners. We do so by conducting a short network survey in a given organization, from which we extract network metrics that may help us with the sampling process. In sum, the difference to the first example is that both strands of research include a relational aspects.

Here, it is important to note that hardly any qualitative procedures originally developed for social network analysis exist (Franke and Wald, 2006). While many tools (e.g., VennMaker by Kronenwett and Adolphs, 2021) and original qualitative social network research methods (e.g., qualitative structural analysis by Herz et al., 2015) have been developed since the referenced statement by Franke and Wald (2006), this narrow definition would still be *too* narrow to be useful. For this chapter, we stick to the broader definition to be more inclusive.

Next to the narrow and broad definitions given above, it is important to note that SNA has sometimes been described as an inherently mixed method (cf. Onwuegbuzie and Hitchcock, 2015). As argued before, this description makes sense if compared to more “traditional” quantitative methods, as social network analysis adds a new quality to the data through its interdependent cases and mixes attribute data (e.g., the gender and age of pupils) with relational data (e.g., friendship relationships between the pupils). But for the scope of this chapter, this definition is not useful, as it would equate MMSNA with social network analysis, in general. As we point out in the next section, the term “social network analysis” without any further description as “qualitative” or “mixed” often means quantitative social network analysis in the literature. For example, see the definition of Freeman (2004), that explicitly includes the use of mathematical/computational tools as one of four defining factors of social network research.

Why MMSNA? A brief methodological history of (mixed methods) social network analysis

The necessity of MMSNA and the gaps that it fills in contemporary social network research is best understood if taking a brief look at the history of social network analysis. Simplifying the seminal article about the history of social network analysis by Freeman (2004; also see Onwuegbuzie, 2020), we can see three phases, which can be mapped to a predominant methodological approach: qualitative, quantitative, mixed.

Qualitative beginnings

The first phase spans most of the 20th century, when early social network methods were being proposed by Moreno and his colleagues (Moreno, 1934). While these methods of “sociometry” have been predominantly of qualitative nature at this time, it is important to note that social network analysis was not very often applied in absolute terms. Here, the sociogram first appeared as a way to illustrate *abstractions* of relationships to make sense of them and the network they make up (for the role of abstractions, the interested reader may also refer to the Euler’s solution to the “Seven Bridges of Königsberg” (Euler, 1956), which is often regarded as the very first application of social network analysis in 1736). As a sidenote, visualization could be seen as another feature that is prominent both in mixed methods and social network analysis (Shannon-Baker and Edwards, 2018; Shannon-Baker and Hilpert, 2020).

Increasing adoption of quantitative social network analysis

The application of social network methods picked up pace toward the end of the 20th century, when masses of quantitative, relational data became more readily available through advances in technology. Especially the advent of the Internet further increased the volume of studies produced based on social network analysis (e.g., Twitter networks; Brantner and Pfeffer, 2019). In this time, the qualitative roots of social network analysis seem to have been largely forgotten and quantitative methods based on graph theory in mathematics (Barnes, 1983) became the new (and largely unquestioned) standard. With this new method at hand, a host of new research questions could be answered, which further increased the prominence of social network research. It is worth pointing out that the development of this new field of research was largely driven by technological and mathematical advancements and data availability, other questions, such as having solid theories about social networks, were mostly dealt with at a later stage. This also led to the then common perception that social network analysis is void of theory. This perception persisted also in later decades. But with a plethora of original network theories available (Borgatti and Halgin, 2011; Fuhse, 2020; Monge and Contractor, 2003), this statement can nowadays hardly be accepted as true.

Importantly, this was also a time for social network analysis to be increasingly used across academic disciplines. Indeed, there hardly is an academic faculty in which social network analysis and its general and abstract language cannot be applied. In education science, social network analysis was readily adopted to inform a new branch of (social) learning research of, for instance, pupils (e.g., Pearson and Michell, 2000), teachers (e.g., Moolenaar, 2012), or institutions (e.g., Daly and Finnigan, 2010). The adoption of social network analysis in the domain of education science can be sketched through a quick search in the ERIC database: While only 37 social network-related publications were identified for the year 2003, this number rises to more than 400 only a decade later.

Critique and integration of qualitative and quantitative methods

With the rise in popularity across disciplines, criticism against the highly technical and quantitative nature of social network analysis rose, too (Froehlich et al., 2020d). This criticism was first voiced in sociology and was then carried over to the field of education. These are also the two fields in which edited volumes about MMSNA emerged; first in sociology (Domínguez and Hollstein, 2014) and later in education (Froehlich et al., 2020c). Next to MMSNA, also standalone qualitative research designs were increasingly propagated (Herz et al., 2015; Hollstein and Straus, 2006). The general claim was that the quantitative methods cannot adequately capture the complexity of the research questions used in these fields. For example, quantitative social network analysis can give us a lot of insight into how the social structures of pupils in a classroom looks like. But it does tell us little about, for example, how network configurations fluctuate across time, what content is shared between two actors (and why it is shared), what the qualitative consequences of certain positions in the network are for individual pupils, or whether the classroom per se is actually the right network to study for some pupils, who may have found their friends in other contexts. Put succinctly, Crossley’s (2010) concern is “that the quantitative tools of [social network analysis] process the hurly burly of social life in such a way as to create a very abstract, formal and structural mapping [... that] is too abstract, overly formal and insufficiently attentive to inter-agency and process” (p. 2).

MMSNA in educational research

In this section, we dive into the current state of the art of MMSNA research within education science. Specifically, there are three main questions that we seek to answer:

1. How prevalent is MMSNA in empirical educational research?
2. What methods are being integrated in MMSNA designs?
3. What are the methodological topics that are being discussed within this domain?

Prevalence of MMSNA in education research

A recent systematic review by [Froehlich et al. \(2020a,b,c,d,e\)](#) investigated the usage of MMSNA in education science, highlighting not only the prevalence of application but also its purpose for answering the research question, design features, and the quality of mixing. In the end, 52 studies were included in the review. The prevalent contexts of use were K-12 (23 studies, 44%), higher education (18 studies, 35%) and school administration (three studies, 6%). The main *purpose of mixing* consisted in follow-ups (32 studies, 62%), followed by the purpose of comparison (21 studies, 40%) or a combination of these purposes (eight studies, 15%). Four studies (8%) used mixing to develop one method from the other, and another four studies (8%) did not include reasons for mixing. Regarding the *timing of mixing*, eighteen studies (35%) had parallel designs, of which fifteen used methods that were dependent on each other. 34 studies (66%) had a sequential design, with only six using dependent methods.

Many of the MMSNA studies used network maps (also called sociograms) as a way to illustrate the findings, give feedback to participants, or as a basis to develop interventions. Prominent stages where methods were integrated were the sampling stage, the analysis of results, and the discussion/conclusion part. The review also included an assessment of the quality of mixing present in the reviewed studies based on the Mixed Methods Appraisal Tool ([Hong et al., 2018](#)). Common shortcomings were not explicating the reason for using quantitative and qualitative data and/or methods, the lack of integration of outputs (“meta-interference”), and the often missing elaboration of how and why qualitative and quantitative procedures come to different conclusions.

Methods integrated in MMSNA research designs in education research

Another type of systematic review conducted by [Froehlich \(2020b\)](#) used social network analysis to study how methods of data collection and analysis were connected to each other in educational MMSNA studies. Forty-four papers were included in the review. In these publications 32 different methods were mentioned and 287 relationships were coded, which by the aggregation of the ties (e.g., if two studies were coded to show a sequence of X to Y, this would result in a weight of “2”) resulted in 98 ties total. Based on the visualization of the coded method data as nodes and their connections, there are clear separations between methods that are (1) used very often, like the calculation of basic network metrics, sociometric surveys, and semi-structured interviews, (2) applied with moderate frequency, including group interviews and quantitative content analysis, or (3) hardly integrated with each other, such as video analysis, multilevel modeling or exponential-family random graph models.

These methods were then grouped using modularity algorithms (i.e., algorithms highlighting subgroups of nodes), which identified three subgroups: One subgroup of largely quantitatively oriented methods, such as surveys or communication logs for data collection and calculation of network metrics and correlations for data analysis, one subgroup of largely qualitatively oriented methods, such as semi-structured interviews and observation for data collection and thematic analyses and grounded theory for data analysis, and one subgroup that contained both quantitative and qualitative but rarely used methods, such as qualitative and quantitative content analysis or exponential-family random graph models.

Current debates

In this section, we focus on a selected number of topics that are discussed in the current debate about MMSNA.

Data collection and research designs

Social network analysis has strict data requirements ([Wasserman and Faust, 1994](#)) and there is a long-standing debate about data collection related questions such as measurement validity and the boundaries of a network (e.g., [Burt et al., 2012](#); [Längler and Froehlich, 2022](#); [Laumann et al., 1983](#); [Marsden, 1990, 2003](#)).

Introducing mixed methods to social network analysis has been relevant for both of these exemplary debates, as mixing has been used to inform the crucial boundary decision ([Smith, 2016](#)) or make more valid measurements through including multiple perspectives during data collection ([Längler et al., 2020](#)). The debate about how to make valid measurements also triggered a formalization of specific techniques of relational data collection, for example interviews ([Van Waes and Van den Bossche, 2020](#)) or ethnographies ([Sarazin, 2020](#)). Also, it is a useful approach to measuring and analyzing networks at multiple units of analysis ([Bolibar, 2015](#); [Froehlich et al., 2020b](#)); after all, quantitative methods of social network analysis do have clear strengths when it comes to observing macro-level constructs such as a network’s structure, while qualitative methods of social network analysis may be more useful to investigate individual network members’ views of and actions in the network.

In terms of research designs, there is a notable lack of “prototypical” MMSNA designs that could be used as a point of departure especially for novice MMSNA researchers. One exception is [Froehlich and Van der Wilt’s \(2020\)](#) and [Froehlich’s \(2020a\)](#) attempt to turn [Herz et al.’s \(2015\)](#) qualitative structural analysis into a MMSNA design. Otherwise, a design that could be described as an explanatory MMSNA research design, in which a sociographic survey is followed by in-depth interviews, is a common occurrence in the field of education ([Froehlich, 2020b](#)).

Ethical considerations

Ethical issues have received a lot of attention in social network research (e.g., [Borgatti and Molina, 2003](#); [Hogan, 2021](#); [Kadushin, 2005](#)), as there are several concerns with social network data, for example, in the direction of anonymity and the disclosure of

Fig. 2 Ethical concerns about non-participant data.

information about non-participants. Basically, the problem is that often precise inferences can be made from an individuals' network to the individual. **Fig. 2** shows an exemplary network, which could be about sensitive information such as political or sexual orientation. In this example, A and C have disclosed information about themselves (e.g., a certain political or sexual orientation) and B and D did the same. On the relational level, we only note connections of B and D to our focal actor, X, who did not participate in this fictional study. Even in this simple example, the inference that X will be more similar to B and D (assuming that the relationship describes something positive, such as friendship or frequent information exchange) and less similar to A and C seems likely.

While these concerns are applicable to any social network analysis, MMSNA amplifies these challenges, as even more in-depth information about (non-)participants are being collected. Hence this topic received quite some attention in the work about MMSNA, for example by [Korir et al. \(2020\)](#) or [Onwuegbuzie \(2020\)](#). Unfortunately, limited options exist for a resolution. The researchers could ask for consent also from those individuals that did not participate in the data collection, but who were mentioned by others. But even if consent is not given, it may be a difficult decision to leave out a person from analysis, as this could have a large effect on the overall structure of a network. In the worst case, this could render a dataset worthless for analysis. This dilemma emphasizes the importance of transparently communicating upfront and discussing the ethical challenges with independent reviewers.

Human capital limitations

Another problem that is frequently highlighted in mixed methods research concerns the human capital necessary to execute high-quality mixed methods research (cf. [Onwuegbuzie and Hitchcock, 2015](#)). Compared to mono-method studies, mixed methods studies are more demanding in terms of methodological knowledge. This is because capabilities in qualitative and quantitative methods need to be available, as well as knowledge about how to integrate both successfully. Arguably, this problem is exacerbated in MMSNA for three reasons. First, quantitative social network methods tend to be rather complex and require in-depth knowledge about quantitative procedures. Also, as outlined above, researchers usually do not receive a general training in relational methods, statistical procedures applicable within the field of social network analysis, such as quadratic assignment procedures ([Dekker et al., 2003](#); [Krackhardt, 1992](#)), exponential-family random graph models ([Robins et al., 2007](#)), or stochastic actor-based modeling ([Brouwer and Froehlich, 2020](#)) are usually not discussed in introductory statistics courses ([Froehlich et al., 2020a](#)). At the same time, these highly quantitative procedures often cannot simply be left out, as they contribute valuable structural information about networks. Also, as the field is very much driven by quantitative analyses ([Hollstein, 2014](#)), inclusion of these procedures makes it easier to integrate own findings in to the existing body of knowledge. Here, further standardizing and automating some of the quantitative procedures may alleviate the issue ([Froehlich et al., 2020a,b,c,d,e](#)).

Second, methods of qualitative network research are quite under-developed. While there has been some discussion about why qualitative social network research is important ([Decuyper, 2020](#); [Hollstein and Straus, 2006](#)), much less attention was given to the specification of qualitative research procedures. Hence, individual researchers need to be comfortable navigating this uncertainty by inventing their own procedures on the fly. Also, due to the recency of the last wave of qualitative and mixed methods network research compared to quantitative social network analysis, the (software) tools are often less refined, accessible, or stable than their quantitative counterparts. For example, published lists about software for social network research predominantly focus on quantitative applications (e.g., [Huisman and van Duijn, 2005](#)).

Third, while some publications break down the discussion of how mixed methods might be applied within the context of social network research—as reviewed in this chapter—it needs to be recognized that this strand of the literature is still in its infancy. Here, too, researchers are mostly required to build the path as they go, which again increases the burden for MMSNA researchers.

Practical impact

One emphasis in the educational mixed methods literature is its potential to not only have impact in academia, but to transform practice, too (Mertens, 2007, 2008). This is echoed also in the literature about MMSNA; which has been highlighted as a method highly conducive to deriving practical implications. For example, Palonen and Froehlich (2020) discuss the merits of MMSNA for organizational analysis. One advantage that social network analysis has over other methods of analysis is that it easily provides a novel (relational) perspective to stakeholders, while the visual nature of many (mixed methods) social network studies (Shannon-Baker and Hilpert, 2020) make the data very accessible also to laypersons.

We might also view organizational analysis using social network analysis as an important predecessor of MMSNA, as organizational analysis usually does not stop with a purely quantitative assessment. Instead, quantitative results are contextualized through interviews and workshops with stakeholders, which adds qualitative data (cf. the highly influential managerial book about organizational network analysis by Cross and Parker, 2004). However, we also need to point out that the (quite profound) ethical concerns outlined above are even more pronounced when using the data for other purposes than research (Borgatti and Molina, 2003).

Outlook and conclusions

As presented in the brief historical overview of the evolution of social network research, MMSNA as a concept is a relatively recent idea. While there are some empirical applications in the field of learning and education research (e.g., as included in the systematic reviews referenced above), the methodological discussion is just at the beginning. In this chapter, we have outlined a few strands of the discussion, namely data collection and research designs, ethical considerations, human capital limitations, and the direct impact on practice that MMSNA often seeks to make.

While these discussions are important starting points, they clearly are not conclusive at this point in time. Instead, the debate about how to best fit the idea of mixed methods into the context of social network analysis needs to be further refined. We believe that this may not be only useful for further applications of MMSNA, but it may also lead researchers to address some underdeveloped strands of the general social network literature, for example, reflecting on the very nature of networks, which in quantitative mono-methods studies was often reduced to the perspective of the researchers (thus raising validity concerns).

Another promising avenue for further research about MMSNA has less to do with mixing but with the development of qualitative relational research methods. While publications about social network analysis or publications using social network analysis have enjoyed exponential growth over the past decades, this is only true for quantitative (mostly mono-method) studies. A more coherent set of qualitative data collection procedures and qualitative analytical strategies would help to build a more varied base for future MMSNA designs. This claim can be substantiated by the review of Froehlich (2020b), which has shown that hardly any MMSNA study exists in the field of education that does not rely on some form of questioning (survey or interview).

Glossary

Big data A set of data that is too large and complex for processing by traditional database management or computational tools

Big qual Data sets containing either secondary qualitative data or primary data with at least 100 participants, analyzed by teams of researchers, often funded by a government agency or private foundation, and conducted either as a stand-alone project or in conjunction with a large quantitative study (Brower et al., 2019)

Elicited data Data collected by posing questions or prompts to human participants. These methods include interviews, focus groups, or surveys

Enacted methods Data collected through experiential activities such as creative or arts-based methods, participant observations, or simulations

Extant data Data that exists without intervention by the researcher

Methods Procedures or techniques used to implement the sampling, data collection, or data analysis steps within a research study (Plano Clark and Ivankova, 2016)

Methodology The process of research from formulating questions to drawing conclusions in a study (Plano Clark and Ivankova, 2016)

Mixed methods research A term used for the process of research when researchers integrate quantitative methods of data collection and analysis and qualitative methods of data collection and/or analysis (Plano Clark and Ivankova, 2016)

Mixed-reality world A term used to describe living with online and technology-assisted experiences in conjunction with life in the physical world

Multimethod research A term used for the process of research when researchers integrate multiple quantitative approaches, multiple qualitative approaches, or multiple quantitative and qualitative approaches (Plano Clark and Ivankova, 2016)

Research design A thoughtfully constructed link between the purposes of a research study and the strategies used to implement it (Creamer, 2018)

Research paradigm The collection of assumptions and values about the nature of reality and knowledge that provide the foundation for a research study (Plano Clark and Ivankova, 2016)

Secondary data Data that have already been collected for some other purpose. In this chapter, secondary chapter is referred to as extant data

Introduction

We need mixed methods to study a mixed-reality world. Activities associated with independent and classroom learning, reading and study, discussion and collaboration have changed profoundly with widespread adoption of the internet and related information and communications technologies (ICTs). To understand the experiences and dilemmas of digitally-oriented modern life, we need to re-think methods for planning studies and collecting data.

Quantitative and qualitative researchers view this challenge of studying technology-infused lived experiences differently. The ever-growing use of online communication and social media—and the resulting big data—excites quantitative researchers who can scrape and download secondary data rich with potential relationships and correlations. Quantitative researchers are glad to access diverse participants for online surveys or experiments. Similarly, the ability to use online communication and social media to create deep exchanges with research participants across the globe—the humans on the other side of the monitor or device—excites qualitative researchers. Nevertheless, the line between qualitative and quantitative methods is blurring. Qualitative approaches, termed *Big Qual*, are being used to analyze large bodies of content previously associated with quantitative studies (Brower et al., 2019). Meanwhile some quantitative researchers are realizing that “experts with deep knowledge of a subject are needed to ask the right questions and to recognize the shortcomings of statistical models”. Sometimes in the midst of a sea of data, the quantitative researcher needs to stop and ask individual participants, “why?” When researchers mix qualitative and quantitative methods, online and in-person approaches, they have the ability to study the rich complexity of contemporary life with research that is big in scope and deep in meaning. This chapter focuses on emerging ways to mix qualitative and quantitative methods in studies that make use of the internet, applications on devices, or other ICTs for data collection.

Collecting data online

We will broadly define mixed methods as the “intentional integration of quantitative and qualitative research approaches to best address a research problem” (Plano Clark and Ivankova, 2016). In short, integration of methods is not limited to the collection of different types of data. In some cases, it is not the nature of the data itself that signifies whether the study is deemed qualitative or quantitative, but the way the data are analyzed and used within the study. For example, in mixed methods studies stories collected with qualitative approaches can be coded and analyzed with statistical methods, and narrative stories can be told based on statistical findings drawn from quantitative studies. While mixing methods means thinking and re-thinking all aspects of research from initial formulation of questions through analysis and reports of findings, this chapter centers attention primarily on data collection.

For the purpose of this chapter, we recognize that the source and setting of the study are noteworthy when we consider ways to use the digital environment in data collection for mixed methods research, and will use this definition:

Conducting mixed methods online means the researcher intentionally selects and integrates quantitative and qualitative data collected on the internet, through applications or platforms, or using other information and communications technologies (ICTs) to best address a research problem.

Collecting qualitative and/or quantitative data online

Clearly, the simplistic conceptions of qualitative data as words and quantitative data as numbers are inadequate when considering the wide variety of source materials and interactions that are possible in the digital world. One way to categorize data collected is by the type and degree of relationship between the researcher and the source of the data. As illustrated in Fig. 1, researchers have three options for using qualitative or quantitative methods to collect or generate data that correspond to close or distant relationships between the researcher and source(s) of data.

The first option is to use extant data, that is, data that exist without intervention by the researcher. Extant data were created for another purpose but is available to the researcher. The researcher can find extant data on the public web, in libraries or archives, private collections, organizational or government records. It can take many forms, from casual posts to well-researched scientific reports, from personal diaries to large-scale datasets. Some extant data are readily available, other types might require permissions to access and use for research purposes.

The advantage of extant data is obvious: the materials already exist. Some are in written form that means transcriptions are not necessary, and media posted in many libraries include transcriptions. The popularity of user-generated posts and comments means all kinds of perspectives can be discovered on open sites, social media, and online groups or communities. The disadvantages are that the materials might not be fully relevant to the research problems, might be incomplete, or lack context.

The second type of data are elicited from participants. Whether using a quantitative instrument for an online survey to be completed by hundreds of respondents or interviewing twenty participants on a videoconferencing platform, these methods invite responses to researchers’ questions. The advantage of this kind of data is the focused relevance to the research problem, and greater degree of control by the researcher than is possible when using extant data. The disadvantage is that participants must be found, recruited, and they must consent to contribute to the study.

The third type of data collection, enacted methods, takes a different tack with participants. While still eliciting responses, rather than asking questions, the researcher creates some way to generate data through some kind of activity. Quantitative researchers conduct experiments, and qualitative researchers use arts-based, creative, or participatory methods. Some studies using enacted methods consider participants as collaborative partners or co-researchers. The advantage of methods in this category is that they can produce rich, substantial data that can produce substantive findings. The disadvantage is that general, enacted methods expect

Typology of Online Methods (Salmons, 2022)		Data collected online from:	Researcher & Participant
Extant	Studies using existing materials developed without the researcher's influence.	• Blogs, websites, or posts on social media. • Published literature, reports, or documents. • Archived materials, records, film or video. • Databases, datasets or Big Data. • Unobtrusive observation.	No direct contact with individual participants.
Elicited	Studies using data elicited <i>from</i> participants in response to the researcher's questions/prompts.	• Interviews, 1-1 or group. • Focus groups. • Written interviews, questionnaires, or surveys. • Participant observation of events or communities.	Interaction between researcher and one or more participants
Enacted	Studies using data generated <i>with</i> participants during the study.	• Vignette, scenario, or problem-based interviews. • Games, simulations or role plays. • Arts-based or creative methods. • Experiments or Field experiments. • Participatory Action Research.	Multiple interactions and collaboration involving researcher one or more participants

Fig. 1 The typology of online methods (Salmons, 2022).

a greater commitment from participants than do elicited methods and might involve a multi-stage process that lasts a period of time.

Researchers can mix qualitative and quantitative data collection approaches across the extant, elicited, and extant types of data collection. Researchers might use one method to gain insights or understanding about the problem, and another method to inquire about how people experience the problem. These three open-access articles offer examples that mix qualitative and quantitative approaches for extant, elicited, and/or enacted data collection:

- **Qualitative Elicited and Quantitative Enacted Data Collection** The first example is: "College Students and Yik Yak: An Exploratory Mixed-Methods Study" (Clark-Gordon et al., 2017). In this study researchers began with a qualitative, elicited stage by interviewing a group of participants about their use of a social media platform. Researchers asked participants to respond and self-report their experiences on a smartphone application. In the second quantitative stage, they used extant data in the form of posts ($n = 3905$) for a content analysis.
- **Quantitative Elicited, Quantitative Extant, and Qualitative Elicited Data Collection** The second example is: "International Platforms, International Prejudice in the Platformization of Crafting" (Close and Wang, 2020). In this study researchers began by eliciting data with an online survey. They conducted a discourse analysis of extant data in the form of online posts, then elicited data with qualitative interviews.
- **Quantitative Extant, Qualitative Elicited, and Qualitative Extant Data Collection** The third examples is: "Ghosts of white methods? The challenges of Big Data research in exploring racism in digital context" (Nikunen, 2021). After analyzing extant big data, the researchers elicited data by interviewing the founder and participants of the project under investigation and using an ethnographic qualitative approach to study a selection of postings.

Mapping potential ways to mix method

To illustrate some of the many ways researchers can mix methods to collect or generate different types of data online, Figs. 2–5 show four hypothetical research designs.

Fig. 2 shows stages in an online mixed methods study that with extant quantitative methods using datasets to gain large-scale sense of trends, and interviews to elicit stories and personal experiences from a small set of participants.

Fig. 3 shows stages in an online mixed methods study that uses qualitative methods to elicit insights and find background about trends in extant data, and a quantitative survey to elicit responses that will make it possible to evaluate the extent to which those insights are common to a larger population.

Fig. 4 shows stages in an online mixed methods study that uses quantitative survey methods to elicit responses that will help to identify trends, and arts-based qualitative enacted methods to generate visual representations of participants' experiences.

Fig. 2 Quantitative extant and qualitative elicited methods.

Fig. 5 shows stages in a hypothetical online mixed methods study that uses quantitative methods to elicit responses with a survey, experimental quantitative enacted methods to measure types of participant experiences, and qualitative interviews to elicit verbal explanations.

Defining ways to mix methods and milieux

Mixed methods researchers have classified some common design types and created a notation system as a concise way of signaling which one is being used. The two main classification factors are *priority* and *timing*, and we will add a third: *milieu*. The milieu refers to the setting where the data is collected. For the purpose of this chapter, research activities occurring in the same physical location are referred to as *in-person*. Research activities that use technology tools are referred to as *online*. See Table 1 for a description of option.

Priority

Priority refers to the degree of dominance of one method over another. Creswell et al. (2003) explain:

The mixed methods researcher can give equal priority to both quantitative and qualitative research, emphasize qualitative more, or emphasize quantitative more. This emphasis may result from practical constraints of data collection, the need to understand one form of data before proceeding to the next, or the audience preference for either quantitative or qualitative research. In most cases, the decision probably rests on the comfort level of the researcher with one approach as opposed to the other.

Creswell et al. (2003).

It is important to communicate the emphasis or balance of methods to the reader. In the notation system developed by Morse (1991), the dominant method used is shown with all capital letters: *QUAL* or *QUAN*. In a study where both methods are equally important, both are capitalized; if one is more important, that term is capitalized while the supportive or secondary type of data is shown in lower case: *qual* or *quan* (Morse, 1991). For example, if I am conducting a small number of qualitative interviews to identify issues I want to explore widely in a large-scale quantitative survey, I might describe the interview part as *qual*, because it is minor stage of the study, and the survey part as *QUAN*, because it is a more significant part of the research. Or, if the interviews and survey have equal importance, I would indicate that by labeling the stages as *QUAL* and *QUAN*.

Timing

The second factor is timing. Morgan identified two core assumptions: that in addition to degrees of priority for qualitative or quantitative methods, the designs varied in terms of a sequence of collecting quantitative and qualitative data (Morgan, 2007). Options are:

Fig. 3 Qualitative extant and quantitative elicited methods.

Fig. 4 Quantitative elicited methods and qualitative enacted methods.

- Concurrent, or simultaneous, meaning both kinds of research are occurring at the same time. This is indicated with a +sign. For example, if I am conducting qualitative interviews while waiting for responses from a quantitative survey, I can describe two types of data collection as concurrent.
- Sequential, meaning the researcher collects and analyzes one kind of data before another. The next phase builds on the results of the first phase. This is indicated with an arrow →. For example, if I am conducting qualitative interviews to identify issues I want to explore widely in a subsequent quantitative survey, I can describe two types of data collection as sequential.

Milieu

The milieu is an additional factor that is important to indicate when classifying a study that includes a setting important to the design of the research. A study could have all parts of the study in one setting or take a hybrid approach. All parts of the study could be conducted online or using an app or other technology tool, or with a hybrid approach using some data collected online and some collected in-person.

The examples illustrated in Figs. 2–5 offer just a few combinations of data collection types with qualitative and quantitative data collection that occurs in a digital milieu. The surveys could be conducted with a tool such as Qualtrics or Survey Monkey, and potentially use a panel of respondents recruited by those companies. Private, proprietary applications or platforms could be used for the enacted research events. Interviews could be conducted using videoconferencing tools such as Zoom™, Skype™, or Teams™, or researchers could collect data by sending written questions by email.

Researchers could also mix online data collection activities with face-to-face approaches. As shown in Fig. 6, some stages could collect data from a larger population online, while other stages involve local participants in-person and online. The potential for combinations means these methods is limited only by the researcher's imagination and energy!

For the purpose of this chapter, we will signal that the data were collected online by prefacing the method with an "o," and if the data were collected in-person with a "p." We will use the same capitalization convention, with the dominant form noted with a capital letter. Using the same example, if I am conducting online qualitative interviews and an online quantitative survey, I can describe two types of data collection as *o-qual* and *o-quan*. Alternatively, if I am conducting qualitative interviews in-person and an online quantitative survey, I can describe two types of data collection as *p-qual* and *o-quan*. Again, use capitalization to show equal or different levels of priority within the study. Table 1 illustrates online and hybrid milieu mixed methods design options for collecting data.

Analyzing mixed online and hybrid studies

How do researchers mix methods and combine different research paradigms when some or all of the data are collected online? Let's examine some published studies to see what approaches are used, and why the researchers chose to use mixed methods. These examples demonstrate how the methodological concepts introduced in this chapter have been used in contemporary research.

Fig. 5 Quantitative elicited methods and qualitative enacted methods.

Table 1 Communicating online and hybrid milieu mixed methods designs.

<i>Design notation</i>	<i>Explanation</i>
QUAL + QUAN	Qualitative and quantitative parts of the study have equal weight, and both parts of the study are conducted in the same time frame.
O-QUAL + O-QUAN	Qualitative and quantitative parts of the study have equal weight, and both kinds of data are collected online in the same time frame.
O-QUAL + o-quan	Qualitative and quantitative data are collected online in the same time frame. The qualitative part of this study is more significant than the quantitative part.
o-qual + O-QUAN	Qualitative and quantitative data are collected online in the same time frame. The quantitative part of this study is more significant than the qualitative part.
O-QUAL + P-QUAN	Qualitative and quantitative parts of the study have equal weight, and both kinds of data are collected in the same time frame. The qualitative data is collected online; the quantitative data is collected in-person.
O-QUAL + p-quan	Qualitative and quantitative data are collected in the same time frame. The qualitative data is collected online; the quantitative data is collected in-person. The qualitative part of this study is more significant than the quantitative part.
o-qual + P-QUAN	Qualitative and quantitative data are collected in the same time frame. The qualitative data is collected online; the quantitative data is collected in-person. The quantitative part of this study is more significant than the qualitative part.
QUAL → QUAN or QUAN → QUAL	Qualitative and quantitative parts of the study have equal weight, but one type data is collected before the other.
O-QUAL → O-QUAN or O-QUAN → O-QUAL	Qualitative and quantitative parts of the study have equal weight, and both are collected online, but one type data is collected before the other.
O-QUAL → p-quan	Qualitative data are collected before quantitative data. Qualitative data take priority and are collected online. Quantitative data are collected in-person.
O-QUAL → o-quan	Qualitative data are collected before quantitative data. Qualitative data take priority. Both types of data are collected online.
P-QUAL → o-quan	Qualitative data are collected before quantitative data. Qualitative data take priority and are collected in-person. Quantitative data are collected online.
O-QUAN → p-qual	Quantitative data are collected before qualitative data. Quantitative data take priority and are collected online. Qualitative data are collected in-person.
O-QUAN → o-qual	Quantitative data are collected before qualitative data. Quantitative data take priority. Both types of data are collected online.

Fully-online mixed methods studies

The first example describes a mixed method study with all data collection carried out online. The article, “Student’s experiences with online teaching following COVID-19 lockdown: A mixed methods explorative study” (Almendingen et al., 2021) reports on a study that collected data from two questionnaires and an online focus group. Questionnaires were sent to participants in a class on weeks two and twelve of the online class, followed by interviews. The researchers described it as a “a mixed methods cross-sectional design, where quantitative and qualitative methods complemented each other” (p. 3). They also pointed out that “[s]ince the study is exploratory, we had not planned the data collection in order to test hypotheses. The study seeks to provide a snapshot in time of an evolving situation” the sudden shift to online learning (p. 14). So while this was a mixed methods study, the researchers used descriptive analysis of the quantitative side, and did not complete a full statistical analysis of the data.

Here is the sequence of data collection stages:

1. The researchers adapted an existing instrument with Likert-scale and open-ended queries. They used quantitative and qualitative questions in the same online questionnaire to elicit data. Respondents could complete it using a browser on a computer, mobile phone or tablet.

**Fig. 6** Mixing methods and milieux.

2. The researchers followed with a second questionnaire to elicit more detailed participant responses.
3. The researchers conducted focus group interviews online in the third phase. The researchers used qualitative methods to elicit data online using a videoconferencing platform. Interviews were not recorded to preserve anonymity, so the moderator's notes served as data.

The data analysis stages progressed the same way, with the quantitative data studied before the qualitative data was coded and summarized. Given this sequence and the discussion of the study where both types of data were equally important, data collection stages could be notated as O-QUAN → O-QUAN → O-QUAL.

Another fully-online study is reported in the article, "Harnessing Technology for Research During the COVID-19 Pandemic: A Mixed Methods Diary Study Protocol" (Saltzman et al., 2021). This article describes a study based on data collected from qualitative diary entries and a quantitative survey. Participants were students in a Master of Social Work program, so it was not necessary to go through a laborious recruitment process.

Here is the sequence of data collection stages:

1. Researchers elicited responses from student participants using an online survey. These data were used "to supplement and further elucidate the themes that emerged in the longitudinal phenomenological data from the virtual diary entries" (p. 4).
2. The researchers set up an enacted data collection process for a longitudinal 8-week series of video diaries. Once the research team received the survey responses, they arranged eight weekly Zoom™ meetings for each participant. Each week, researchers sent prompts to elicit Participants logged into Zoom™ and recorded their video diary entries. If they entered text in the chat function, their words were used without edits from the research team. The platform generated an automated transcript for each entry.

Data analysis followed the same pattern, with a descriptive analysis of data from the survey, followed by a multi-stage thematic analysis of the qualitative diaries. Given that the study drew from phenomenological methodology and a statistical analysis of the quantitative data was not conducted, it is apparent that the qualitative side took priority. To notate this study, o-quan → O-QUAL seems appropriate.

Hybrid on-and off-line mixed methods studies

It is not always possible to conduct all phases of a mixed methods study online. Hybrid research allows for the advantages of both research modes. For example, the article, "Questioning Assumptions About Online Tutoring" (Wisniewski et al., 2020) describes a "comparative study of face-to-face and synchronous audio-video online tutorials that collected data from writing tutorials, writers' postsession surveys, and interviews with writers" (p. 261). The setting for this study was an online platform the university writing center used for tutorials, which meant it was a familiar tool for participating students. Data were collected by recording online and face-to-face tutorial sessions, collecting postsession writer surveys, collecting tutor logs, and conducting interviews with writers and tutors.

This study was primarily conducted online, with online data collection and use of technology tools for data analytics. One stage, recording tutorial sessions, occurred in-person and while the article does not detail the interview settings it appears that they were conducted in person.

The sequence went as follows:

1. Interviews to pin down existing beliefs about and attitudes toward face-to-face and online tutoring. The researchers used qualitative methods to elicit data.
2. Recording online and face-to-face tutorial sessions. The researchers used qualitative enacted methods with recorded events.
3. Anonymous survey. The researchers used quantitative methods to elicit data.
4. Interviews. The researchers used qualitative methods to elicit data.

The data analysis stage was also sequential:

1. Coding session transcripts to generate categories of instruction within the tutorials (qualitative)
2. Coding tutorial topical content (qualitative)
3. After establishing codes and counts, the researchers created an SPSS dataset and used it to analyze mean differences between variables in the two online and face-to-face sessions (quantitative).

Given that three of four data collection methods were qualitative, and two out of three data analysis stages used qualitative methods, we can surmise that the capitalization for QUAL and quan reflects the researchers' priorities. The sequence of on- and off-line stages of data collection could be notated as: O-QUAL → P-QUAL → o-quan → O-QUAL. The stages of data analysis could be notated as: O-QUAL → o-quan.

The article, "Stress and family relationships among college student parents: A mixed methods study" (Dotterer et al., 2020) explores research using a concurrent mixed methods design. Participants completed an online survey and in-person semi-structured interviews. Demographic and financial income information were also collected about the participants.

While the researchers described the study as "concurrent," they describe research stages as:

1. Completion of an online survey. The researchers used quantitative methods to elicit data.

Table 2 Published examples of online and hybrid mixed methods designs.

<i>Design notation</i>	<i>Citation</i>
Data collection: O-QUAL → P-QUAL → o-quan → O-QUAL data analysis: O-QUAL → o-quan	Wisniewski et al., 2020
Data collection and analysis: O-QUAN + P-QUAL.	Dotterer et al., 2020
Data collection and analysis: O-QUAN → O-QUAN → O-QUAL.	Almendingen et al., 2021
Data collection and analysis: o-quan → O-QUAL	Saltzman et al., 2021

2. In-depth interview conducted in-person with a small subsample of the population. The researchers used qualitative methods to elicit data.

The analytic process similarly progressed in two stages:

1. Descriptive analysis and regression analysis using SPSS with survey data (quantitative)
2. Thematic analysis using interview data (qualitative).

Based on the information provided in this article, this study balanced the qualitative and quantitative priorities in both data collection and analysis so the QUAL and QUAN would be accurate. The study also mixed an online and an in-person stage of data collection. The notation that summarizes the research as described in this article is: O-QUAN + P-QUAL.

Learning from examples

The styles used in this small collection of studies are summarized in [Table 2](#).

Given the time frame for the research described in these four studies, at the advent of the Covid-19 pandemic, the researchers took advantage of the opportunity to collect some or all of the data online. Given this situation, their rationales for carrying out their respective studies could be described as convenient. They had limited options for collecting data face-to-face. That said, the researchers discovered the value of using technology tools, such as automated transcriptions or the ability to reach participants in relaxed settings. [Table 2](#) shows research examples for online and hybrid milieu mixed methods designs.

Summary: online mixed methods researchers have many options

This chapter introduced a range of possibilities for combining qualitative and quantitative methods and for using technology. By mixing qualitative and quantitative data at various stages of the study, researchers can dig deep and explore broadly. Researchers also need to explain complex studies in ways readers can understand. The Typology of Online Methods ([Salmons, 2022](#)) and notational system articulated by Morse in 1991 and modified here to recognize the online or in-person setting, provide ways to succinctly communicate web-based research designs.

Online research offers researchers the ability to visit libraries and archives to discover historical and contemporary materials, conduct interviews, observations, questionnaires, and surveys without leaving their offices. Researchers can reach across the globe or collect important local perspectives. They can tap into culturally-rich ways people experience some event by scraping massive numbers of posts to social media sites or ask someone about their singularly unique experience.

With so many options, you will need to be able to make design choices appropriate to the research purpose and intentionally determine which types to use. Begin by learning how each paradigm works, and the strengths and limitations of each. Then look at how you can bring the most useful mode of inquiry into your own research plans.

Introduction

Some knowings cannot be conveyed through language.

Elizabeth Ellsworth (2005, p. 156).

As educational researchers study increasingly complex phenomena and educational contexts (Poth, 2018), they need methods that are expansive enough to explore those complexities. Mixed methods studies that integrate art (e.g., dance, painting, photography, creative writing) and artistic practices (e.g., keeping a visual journal, experimenting with art techniques) can meet this need. The purpose of this chapter is to introduce how and why educational researchers integrate art and artistic practices into mixed methods research (MMR) studies. We first define several key terms including arts-based, arts-informed, and other arts-related research approaches and MMR. We then highlight several studies to demonstrate how educational researchers have used the arts in different ways and their rationales for including/integrating art. Additionally, we identify several challenges facing researchers who aim to integrate art in MMR including strategies to address each.

Methodology, design, or methods: bringing arts-related and mixed methods research together

It is important to first differentiate between research methodology, research design, and research methods. *Research methodology* refers to the overarching framework of values and practices related to the research designs and methods that a researcher uses. Examples of common research methodologies include qualitative research, quantitative research, arts-based research, and MMR. Although connected to philosophical paradigms such as constructivism, pragmatism, postmodernism, etc., researchers can use a specific research methodology with multiple paradigms (cf. Shannon-Baker's chapter on philosophical paradigms in this volume). Within a research methodology or across multiple methodologies are the *research designs*, or the specific frames that guide and organize specific research methods. Example qualitative research designs include case study, ethnography, critical discourse analysis, etc. Example mixed methods designs include sequential explanatory or exploratory, concurrent/convergent parallel, etc. (Creswell and Plano Clark, 2017; DeCuir-Gunby and Schutz, 2017). Within a research design are *research methods*, or the specific practices, techniques, and procedures to collect, analyze, and interpret data. For example, a case study design might use research methods such as

*Corresponding author

individual interviews, focus group interviews, and deductive coding of the data to compare across cases. **Fig. 1** displays how these three frames are interconnected. This figure depicts research methodology providing the overarching frame that encompasses both research design and research methods. Although research methodologies might determine particular research designs and research methods, these are not static categories. Some methods and designs cut across multiple methodologies, signified by the dashed arrows.

In the following sections, we provide a foundation for defining and characterizing the following: various forms of arts-related research including arts-based and arts-informed research, MMR, and both arts-based mixed methods research and arts-informed mixed methods research.

Framing various forms of arts-related research

We use the term *arts-related research* to capture the wide range of research forms that use art and artistic practices, where art refers to the product or material created (e.g., a painting, performance, poem) and artistic practice refers to the process of creating and interpreting art (e.g., painting, performing, writing poetry). Although some researchers have dated the use of arts-related research approaches in social sciences back to the 1970s with the work of Elliott Eisner and Maxine Greene (Sinner et al., 2006), art was considered research long before. For example, Pablo Picasso stated, “I never made a painting as a work of art, it’s all research” (as cited in McNiff, 2008, p. 29). Here Picasso is referring to the process of engaging in artistic practices including studying and practicing techniques in an art form, experimenting with different forms and format, and studying the topic that will be portrayed in the art.

Arts-based research has been characterized as a “set of methodological tools” (Leavy, 2009, p. ix), as living inquiry (Irwin and Springgay, 2008) and a “dynamic process of inquiry” (Sinner et al., 2006, p. 1229). For the purpose of this chapter, we conceptualize *arts-based research* (ABR) as a research methodology where artistic practices are deeply integrated in and central to the entire research process (Austin and Forinash, 2005; Leavy, 2009; Sinner et al., 2006; Slattery, 2003). In ABR, some practitioners differentiate between practices and methods: “Practices may involve a range of activities at the center of research, such as customary approaches to art-making, creative rituals, original performances [...]. In contrast, *methods* suggest a more traditional research orientation involving” sampling techniques and data collection procedures and products (Sinner et al., 2006, p. 1229). These artistic practices might include but are not limited to the creation of artistic pieces—literary, visual, and performative—as data, analysis, and/or sharing research results; intensive reflection on the researcher’s and participants’ subjectivities; and heightened concern about form, representation, and creation of art pieces. ABR emphasizes inquiry, ambiguity, open-endedness, and fluidity (Eisner, 2008; Ledger and Edwards, 2011), the practices, processes, and products of research (Sinner et al., 2006), and is often participatory in nature (Estrella and Forinash, 2007). Researchers might use arts-based research for a variety of reasons. They may seek to use “alternative formats to evoke or provoke understandings that traditional research formats cannot provide” (Sinner et al., 2006, p. 1225). ABR may also be used to promote agency within communities by offering alternative forms of communication to explore and share ideas and experiences (Lincoln, 1995; Shannon-Baker and Martinez, 2022). Based on the research objectives, arts-based research can attempt to operate within, alongside, and/or against traditional research methodologies and methods. For more introduction to other forms of arts-based research, see the chapters in this volume by Hinekura Smith and Janinika Greenwood.

Similar to arts-based research, *arts-based educational research* (ABER) reflects the use of arts-based approaches specific to educational research. (Barone and Eisner, 2006), former student and teacher considered among the founders of ABER, state that ABER should specifically consider the format of the final write-up of the research—that it should be “evocative, contextual and vernacular” (p. 97). Examples of ABER include short stories, oral history, auto/biographies, educational criticism, literary essays, theater, and poetry. These writing-based art forms invite readers’ interpretations, utilize metaphors and thick description, and attract diverse

readers. Researchers who use ABER carefully design and plan their use of form and format with the research purpose and audience in mind. Although much of the criteria for evaluating ABER is similar to ABR (e.g., generating new questions, revealing what was previously unknown or little discussed), “incisiveness” is one criterion that differs. According to Barone and Eisner (2006), this criterion refers to the ability of the research to get to the “heart” of the issue, addressing what is educationally significant. For more introduction to ABER, see Largo’s chapter in this volume.

Arts-informed research is distinguished from arts-based research in that it is a research design where art and/or artistic practices are not central to the research process but instead are used to influence another methodological approach or method (e.g., Shannon-Baker, 2015a). Art is incorporated to enhance or supplement the other approach or method such as an interview or survey (Cole and Knowles, 2008). Researchers use arts-informed research to find alternative representations for information and make research studies more accessible. Arts-informed research shares many of the same concerns for integrity and quality as arts-based researchers do, such as the importance of researcher’s self-reflection throughout the process and being open to the creative process in using art. Arts-informed research could address Ardra Cole’s (2004) call for “words plump and dripping with life juice, compelling and evocative images, representations that drew readers and viewers in to experience the research ‘text’” (p. 16). However, arts-informed inquiry differs in its concerns for accessibility for the audience. Whereas arts-based research can create art for the sake of scholarship, or more standalone art pieces based in extensive artistic training (Cahnmann-Taylor, 2007), arts-informed research does not produce art for this purpose. Instead, these researchers are more concerned with the advancement of knowledge than aesthetically advanced art (Cole, 2004; Cole and Knowles, 2008). As a result, some researchers may begin with arts-informed approaches as they develop their technical skills in the artistic practices they use.

Framing mixed methods research

MMR is a philosophically grounded research methodology that meaningfully mixes or integrates two or more methodologies into a single study to enhance, deepen, or complicate one’s inquiry beyond what would be possible through using a single methodology (Shannon-Baker, 2015a; Shannon-Baker and Edwards, 2018). Notably, we do not limit MMR to the mixing of just qualitative and quantitative methodologies as others in the field do (e.g., Johnson and Christensen, 2008; Tashakkori et al., 2021). Instead, we frame MMR as the integration of “two or more methodologies” to be open to methodologies beyond the qualitative-quantitative binary such as arts-based research. For a broader introduction to other ways of defining MMR, see the chapter in this volume by Plano Clark et al. *Integration* refers to connecting, building, merging, or mixing data and/or findings in a mixed methods study (Creswell and Plano Clark, 2017). Through connecting, an initial set of data can be used to identify who to recruit for subsequent data collection, such as using survey findings to recruit for an in-depth qualitative phase. Through building, a researcher uses the findings from one approach to inform another, such as using interview data to create instruments for a second data collection phase. Through merging, a researcher comparatively analyses multiple data sets to explore similarities and differences in the data as well as to corroborate research findings between data sets (Creswell and Plano Clark, 2017). *Data transformation* is a type of integration where one form of data is converted into a different type of data, such as changing interview data into visual or performing art (e.g., Bagley and Castro-Salazar, 2012). One common form of data transformation is *quantitizing* where another data form is transformed into quantitative data to be statistically analyzed (e.g., Akkus, 2013). Integration is possible through the complementarity thesis, which believes that multiple approaches can be integrated to build upon and balance their strengths and limitations (Tashakkori et al., 2021). “If one relies on just one lens of inquiry to view any educational (or other) phenomena, one can never know the extent to which the lens itself distorts what is seen” (Haney et al., 2004, p. 268). MMR is used to investigate complex phenomena and/or contexts that would not be fully honored, captured, or explored through a single methodological approach (Poth, 2018).

Defining arts-based and arts-informed mixed methods research

Arts-based mixed methods research (ABMMR) brings together ABR and MMR to create a philosophically grounded research methodology that meaningfully mixes or integrates arts-based research with at least one other methodology (e.g., quantitative research). Based on the complementarity thesis, this interface builds on the strengths and characteristics of the ABR methodology: centering artistic practices, taking into account form and representation in the art, embracing open-endedness, and engaging in participatory practices (Eisner, 2008; Estrella and Forinash, 2007; Sinner et al., 2006). It also builds upon the strengths and characteristics of the MMR methodology: remaining philosophically grounded, intentionally mixing/integrating multiple methodologies, and bridging multiple methodologies to address complex phenomena and research contexts (Creswell and Plano Clark, 2017; Morse and Niehaus, 2009; Poth, 2018).

We differentiate between ABMMR and *arts-informed mixed methods research* (AIMMR), which is an MMR design that incorporates an art form or artistic practice embedded within another methodological approach in order to supplement or otherwise aid that approach (e.g., Haney et al., 2004; Edwards and Creamer, 2018; O’Connell, 2013). Fig. 2 is one way we envision the differences between AIMMR and ABMMR. On the left side of the figure, AIMMR is portrayed as “air” or arts-informed research as a smaller component embedded in the qualitative strand of a mixed methods study (where the cross sign and double-headed arrow indicate that the mixed methods design could be concurrent or sequential). On the right side of the figure, ABMMR is portrayed where the “ABR” or arts-based research component provides the overarching frame for the whole study. Here qualitative and/or quantitative methods are embedded within this ABR frame. The relationship then for the arts-based research framework to qualitative or

Fig. 2 Visual comparison between arts-informed mixed methods research and arts-based mixed methods research.

quantitative methods could either be concurrent (cross sign) or sequential (double-headed arrow). For visual consistency, we used hexagonal shapes for qualitative research, rectangular shapes for quantitative research, and rounded shapes for the arts-related components.

Researchers may choose an AIMMR approach instead of ABMMR while developing their artistic skills and techniques, when they do not have the resources available to use arts-based approaches, and/or in instances where disciplinary or other evaluative processes are not as supportive as arts-based approaches. For example, Shannon-Baker (2015a) used an AIMMR approach in their study about culture shock among students participating in a study abroad program. In this study, students' self-portraits were embedded in the qualitative strand of a concurrent study that combined qualitative written reflections and a quantitative scale. This study was used as a pilot study for Shannon-Baker's (2015b) dissertation that used ABMMR. Whereas the self-portrait was a smaller component of the pilot study, Shannon-Baker expanded the study to include three self-portraits over the duration of the program to center their descriptive importance in the study. Students also analyzed their own arts-based data from the portraits along with other data. Shannon-Baker used these methodological changes to position the arts-based component as its own methodological strand alongside qualitative and quantitative research, making it a three-strand concurrent mixed methods study.

It is important to note that mixed methods studies about arts-based interventions are not necessarily examples of either AIMMR or ABMMR (e.g., Coppola et al., 2017; Gowda et al., 2018). Making art or artistic practices the topic of a study does not necessarily mean that researchers use that art as part of the methods in their study. Catching this distinction requires a close reading of the reported methods to see if/how art and artistic practices are used in the research methods to determine if a study uses AIMMR or ABMMR approaches.

To compare arts-based, arts-informed, mixed methods, arts-based mixed methods, and arts-informed mixed methods research, see Table 1. This table compares these methodologies across four dimensions: definition, characteristics, rationales for using, and challenges to using.

Integrating art and artistic practices into mixed methods studies in education

Educational researchers integrate art and artistic practices in various ways in their mixed methods studies. To showcase some of these possibilities, we highlight several examples in this section including what art and/or artistic practices were integrated and why.

Embedding art within other methodological approaches: examples of AIMMR

Educational researchers can use an AIMMR approach to integrate art within another methodology. In an example study that resembles a convergent mixed methods design (where both qualitative and quantitative data are collected relatively simultaneously without influencing one another; Creswell and Plano Clark, 2017), Ubha and Cahill (2014) embedded drawings in their qualitative interviews. They studied attachment theory, which looks at how we build relationships with others especially between children and adults, in a primary school context. They implemented a 10-week intervention for five children who had been identified by a teacher as being "passive and withdrawn" from others (p. 6). They evaluated the intervention based on pre- and post-intervention data from quantitative questionnaires and qualitative interviews with the children that included a drawing activity. Ubha and Cahill used the Kinetic Family Drawing activity using the prompt "draw everyone in the family doing something" (p. 8) because drawings are "fun and non-threatening; it also does not require literacy or verbal skills" and because drawings help in "generating and refining hypotheses" (p. 8). This is an example of AIMMR for how the drawings primarily served the qualitative interview as a *visual elicitation method*, or a method that uses visuals (already created or newly created by participants) to promote deeper conversations.

In another AIMMR example, Syeeda (2015) used a mixed methods case study approach (which combines MMR with a case study design that focuses data collection on a specific case; Cook and Kamalodeen, 2020; see also Plano Clark et al.'s chapter on MMR and case study in this volume) to explore secondary students' attitudes toward math and whether their demographics (e.g., age, gender, linguistic background) related to their attitudes. In this example, she included open-ended items in a questionnaire that allowed students to either write or draw their perceptions about math and its impact on their lives. Syeeda included drawings in the study as an "alternative medium of communication [for students] to exhibit their feelings and thoughts" (p. 234). This questionnaire was the second phase of the study that followed initial qualitative focus groups. She found that less than 10% of the 187 students who filled out the questionnaire chose to draw, possibly due to the short amount of in-person time they had to fill out the questionnaire.

Table 1 Comparing arts-based and arts-informed research, mixed methods research, and arts-based and arts-informed mixed methods research.

	<i>Arts-based research (ABR)</i>	<i>Arts-informed research (AIR)</i>	<i>Mixed methods research (MMR)</i>	<i>Arts-based mixed methods research (ABMMR)</i>	<i>Arts-informed mixed methods research (AIMMR)</i>
Definition	A research methodology that centers art and artistic practices throughout the inquiry	A research design that uses art and/or artistic practices to supplement another research methodology or method	A philosophically grounded research methodology that meaningfully integrates two or more methodologies	A philosophically grounded research methodology that centers art and artistic practices from ABR while meaningfully integrating another methodology	A mixed methods research design that uses art and/or artistic practices to supplement another research methodology or method
Characteristics	Create and use art throughout the study; engage in reflexivity; emphasize esthetics; concern about form, representation, processes, and practices; embrace ambiguity and openness	Create and/or use art; engage in reflexivity; concern for the accessibility of art; emphasize art for the purpose of advancing knowledge	Embrace the complementarity thesis; meaningfully integrate data and/or methods through mixing, connecting, and/or building; focus on pragmatic applications	Embrace the complementarity thesis; create and use art throughout the study; engage in reflexivity; meaningfully integrate data and/or methods through mixing, connecting, and/or building; embrace ambiguity and openness with a focus on pragmatic applications where possible	Embrace the complementarity thesis; create and/or use art; engage in reflexivity; concern for the accessibility of art; meaningfully integrate data and/or methods through mixing, connecting, and/or building; emphasize art for the purpose of advancing knowledge
Rationales for using	Provide alternative forms of representation and communication; promote agency especially in marginalized communities/groups	Provide alternative forms of representation and communication especially with those who have limited verbal/language skills; promote agency especially in marginalized communities/groups; use when lacking training, resources, and/or support for ABR	Enhance, deepen, and/or complicate the phenomena being studied; address research contexts and/or design complexities	Provide alternative forms of representation and communication; promote agency especially in marginalized communities/groups; enhance, deepen, and/or complicate the phenomena being studied; address research contexts and/or design complexities; connect art elements and research topic	Enhance, deepen, and/or complicate the phenomena being studied; provide alternative forms of representation and communication especially with those who have limited verbal/language skills; promote agency especially in marginalized communities/groups; use when lacking training, resources, and/or support for ABMMR
Challenges to using	Evaluation of art and artistic practices; amount of aesthetic and arts-based training; mystifying qualities of art; lack of or minimal support for using art and artistic practices; lack of clear terminology in published work	Evaluation of art and artistic practices; amount of art-related training; mystifying qualities of art; lack of or minimal support for using art and/or artistic practices; lack of clear terminology in published work	Time and resources needed to conduct; amount of methodological training in each area used; lack of or minimal support for using multiple approaches in a single study; lack of clear terminology in published work	Amount of training in ABR, MMR, and other approaches used; clarity of methods/practices in published work; lack of or minimal support for ABR and MMR approaches; lack of clear terminology in published work; tension between embracing openness and ambiguity versus pragmatism; lack of consistent evaluation criteria	Training in AIR, MMR, and other approaches; clarity of methods/practices; lack of or minimal support for AIR and MMR approaches; lack of clear terminology in published work; lack of consistent evaluation criteria

(25 min) or because, according to Syyseda, students become “less enthusiastic about drawing as they grow and move up in school” (p. 247). In this case, although Syyseda’s focus in the article is on the importance of using visual data in mixed methods studies in education, making the drawings optional means this study might be better identified as an arts-informed mixed methods study.

Centering artistic practices in a mixed methods study: examples of ABMMR

Educational researchers can also center the artmaking and artistic practices in their mixed methods studies. From nursing education, Ridgway et al. (2018) used a longitudinal mixed methods design to study nurses’ attitudes toward and perceptions of older people during their undergraduate nursing program. Three times per year for three years, the researchers collected data from a survey on attitudes toward older people and a drawing of a person at 75 years of age. The researchers also used a scale on attitudinal change and the drawings as a form of visual elicitation during an interview. These data were collected as part of the students’ coursework and clinical field experiences that included typical content in “aging and disease processes [...] in accordance with the European Union requirements” (p. 64). Although Ridgway et al. used the drawings as a form of visual elicitation, we characterize this study as an arts-based mixed methods study because of the central role that the drawings played in understanding the nursing students’ perceptions.

Ridgway et al. (2018) used drawings and visual elicitation due to the prevalence of visual tropes around aging such as wrinkles, gray hair, and mobility aids. Visuals can help articulate ideas that are difficult to put into words and can help to identify implicit biases (Rose, 2016). Ridgway et al. (2018) analyzed the drawings by identifying broad categories from the visual and/or the accompanying written description. These findings were then integrated through comparison analyses with quantitative findings from the attitudinal change scale and the students’ scores on an attitudinal scale toward older people. These integration analyses identified meta-themes across the three data sets. Findings from analyzing the visual elicitation discussions during the interviews were then used to supplement these meta-themes. Combining visual methods with the quantitative methods “provided a clearer picture” of the students’ attitudes (p. 67). The drawings in particular “provided a powerful discourse relating to the participants’ social constructs of aging” (p. 67).

From the field of dance education (preparing future dance teachers), Wilson and Moffett (2017) evaluated the use of an arts-based research project called “Same Story, Different Countries” that explored racism in the USA and South Africa in a mixed methods study that combined qualitative and dance as an embodied form of arts-based “data collection, analysis, and representation” (p. 139). They combined these approaches for the purpose of triangulation and to address the research purpose through multiple perspectives. Over the 15 months of the project, they collected and analyzed qualitative data included group discussions, reflective writing, document analyses, final project transcriptions, and a final open-ended survey four months later. The arts-based data included “movement exploration, improvisation, performance tasks, embodied storytelling and movement workshops” (p. 139) as well as the final project performance. The research culminated in a 2-h performance that included dance, poetry, music, stories, and visual projections. This study represents the collaborative potential of ABMMR not just across countries but also across professions, combining “choreographers, researchers, educators, visual artists, musicians, poets, and postsecondary dance students” (p. 136). They also found that the arts-based project was a “powerful tool [...] for creating valuable, integrated learning spaces between dance as art and social justice learning, without sacrificing one for the other” (p. 146). They integrated the arts-based approach of dance because it allowed them to integrate “multiple domains of dance learning, knowledge, and practice, teacher and student identities, and connect academics and practitioners across disciplines and communities” between the two countries (p. 146). They argued that integrating arts-based approaches can broaden understandings and possibilities for their field.

Challenges to using and integrating arts-related and mixed methods research

There are many challenges to using arts-related mixed methods approaches for educational researchers to consider. Whereas some challenges speak to both the challenges faced in arts-related research and MMR individually, other challenges come from the potential tensions between integrating these two methodologies. However, we present some strategies for addressing these challenges.

Challenges faced in both arts-related and mixed methods approaches

Level of training

An important challenge in both arts-related and MMR approaches is the issue of training. How much training in the arts is needed? How much training is needed in the other methodologies being used? What about training in mixed methods integration in particular? Some argue for requiring arts-based coursework before using these methods in a study (Piirto, 2002). Art can mystify people (Barone and Eisner, 2006) including those who are asked to make the art as well as the audience for the art. Educational researchers using either AIMMR or ABMMR need to consider their own and the audience’s familiarity and/or comfortability with the artistic practices they plan to use (e.g., Bagnoli, 2009). Researchers can also consider how the design, implementation, and sharing of a study that uses art can help demystify the art aspect (Rolling and Bey, 2012).

Educational researchers may need to spend more time learning and practicing the methods, techniques, skills, and practices they plan to use in an AIMMR or ABMMR study than had they chosen a single methodological approach. However, such educational work need not necessarily be done within a fine arts canon or in formal educational programs. Such stipulations invariably define

whose art practices are legitimate or not (Shannon-Baker and Martinez, 2022). Limited training, at least in the arts-based realm, could be considered a positive aspect; it could limit the bias of the artist in conforming to the expectations of the medium (McNiff, 2008). Without being restricted to the use of specific techniques, arts-related researchers with limited training or those open to veering from method-based norms might be able to develop new methodologies and techniques. However, to more fully consider the ways to methodologically and conceptually integrate art with other methodological approaches, educational researchers need to have some knowledge in the art genre and practices they chose, the other methodological approaches being used, and integration strategies. It is important to note that this challenge faces all mixed methods researchers regardless of whether they plan to use arts-related approaches; mixed methods researchers need to have an in-depth understanding of any of the methodological approaches used to envision the possibilities they have for integrating those approaches.

Clear discussion of methods/practices

Presenting a clear discussion of the methods and/or practices used in an AIMMR or ABMMR study is another challenge facing educational researchers. Grant applications and journals with strict word or page count requirements leave little room to elaborate on all steps in the study. However, without painting a clear picture of the methods, it is difficult for the reader to transfer or replicate the study elsewhere and/or evaluate it (Shannon-Baker and Martinez, 2022). Research diagrams, or visuals that communicate the process and timing for various elements in the research process, can be one helpful way to clearly communicate one's methods in situations where word or page count is limited. Clear diagrams can help identify where and how art and artistic practices are integrated in the study. Additionally, researchers should include explicit rationales behind why particular methods were used (Piantanida et al., 2003). Not only clearly identifying the process but why the researcher made certain methodological decisions provides a series of rationales that can clarify their process to the audience and aid others considering similar methods/practices.

Support for art in a mixed methods study

Whether from supervisors, funders, or publishing outlets, getting support for doing and publishing ABMMR studies can be a challenge. This is because educational researchers who want to use this approach will face others' misconceptions and concerns about both approaches—arts-based research and MMR. Some may perceive arts-based research to lack in rigor, quality, and/or validity (Shannon-Baker and Edwards, 2018). Others have concerns about MMR due to the perceived amount of time and resources needed to conduct such studies rather than using a single methodological approach. These perceptions are due in part to misunderstanding and limited knowledge and/or experience in these methodologies. Similar to the ways in which qualitative and quantitative methodologies have different criteria for judging rigor, quality, and/or validity (or something adjacent), so too do arts-based and MMR methodologies.

To address this challenge, we recommend educational researchers ensure they have a strong grounding in the literature. This literature should help provide rationales and support for choosing an AIMMR or ABMMR approach, how it has been used in the past (or specific methods/practices within the study have been used), and why this approach is best suited for the research purpose and questions. Providing this literature, whether through citations in one's writing or sharing with supervisors, can help address misconceptions and limited knowledge about arts-based, arts-informed, and MMR approaches (and their combinations). When choosing supervisors or research team members, consider what perspective (methodological and otherwise) each brings to the whole of the project. When identifying grant or publishing outlets, consider if they have supported/published works that use arts-based and/or mixed methods approaches.

Using clear terminology

Terminology used is an issue faced in both ABR and MMR approaches (Shannon-Baker and Edwards, 2018). Is the researcher using "art-based," "arts-informed," something else? Is the mixing "mixed methods," "mixed-methods," "multi-method," something else? Using terminology clearly and intentionally helps to align one's research approaches to certain ways of thinking within the field. Also, using clear terminology helps other researchers find studies relevant to their own work (Shannon-Baker and Edwards, 2018). This challenge also addresses how the researcher is theorizing their methods because that connection to other researchers presents one's theoretical and methodological roots for their thinking that then influence how a study develops.

To address this challenge of selecting and using clear nomenclature, we recommend researchers design, implement, and write about their AIMMR and ABMMR studies with a strong grounding in the methodological literature. This starts with presenting clear definitions for both the arts-related and mixed methods approaches being used as we have modeled here. This challenge is made more difficult by the philosophical tension between the embrace of ambiguity in ABR (Eisner, 2008) opposed to the emphasis in MMR for explicit and thorough planning (Creswell and Plano Clark, 2017). In recognition of this tension, researchers may need to be more fluid in their conceptualization of these two approaches or consider adopting a more open-ended definition for MMR (e.g., Greene et al., 1989; Shannon-Baker and Edwards, 2018).

Challenges from the tensions between arts-based research and mixed methods research

Specific to educational researchers who intend to use ABMMR (rather than AIMMR), there are particular challenges that arise from the philosophical and methodological tensions between arts-based research and MMR.

Aim of the research

One tension between arts-based research and MMR is when considering the aim of research. In general, arts-based research tends to inspire more questions than answering questions or providing practical results (Eisner, 2008; Piantanida et al., 2003; Slattery, 2003), although some arts-based researchers have more recently called for more practical applications of this approach (e.g., Eaves, 2014). Conversely, many MMR studies are guided by a pragmatic approach to the research, using the integration of multiple approaches to identify and evaluate practical solutions to everyday problems (Biddle and Schafft, 2015; Johnson and Onwuegbuzie, 2004; Morgan, 2007). This pragmatic approach is particularly present in much of the practitioner-oriented or -initiated educational research. As a result, educational researchers will need to negotiate these philosophical tensions when meaningfully integrating arts-based and mixed methods approaches (Archibald and Gerber, 2018). ABMMR approaches will be especially beneficial if the aim of the study is to explore and/or share counter-narratives from people who have been marginalized (e.g., Bagley and Castro-Salazar, 2012).

Evaluating the research

Another tension between arts-based research and mixed methods research in ABMMR is how to evaluate such studies. Within MMR, several scholars have put forward frameworks that evaluate the clarity of methods particularly during integration and strength of the methodological grounding in defining mixed methods and supporting research decisions (e.g., O’Cathain, 2010; Plano Clark and Ivankova, 2016; Tashakkori et al., 2021). Within arts-based research, there is some debate about the impact of and criteria in evaluating studies. There is some concern that without clear and strong evaluative criteria, arts-based research will glorify “inferior” examples of art (Piirto, 2002, p. 431). Some have argued against firm evaluative criteria for fear that they amount to “methodological policing” (Finley, 2003, p. 284), trying to constrain arts-related approaches within the evaluative criteria established by and for more traditional approaches to research. “If we embrace rigor, if we engage in hegemonic control of the beautiful in research, then we run the risk of missing the opportunity of the dance,” alluding to her epiphanic experience viewing a dance performance (p. 292). Finley argues that trying to validate the arts within a post-positivist framework of science may be futile because these scholars are already biased against it.

Integrating arts-based research and mixed methods research in an ABMMR study will compound these issues. We recommend researchers and their supervisors, reviewers, and evaluators set evaluation criteria that are more contextual to the given study. For example, these criteria can be based on the goal and perspectives/frameworks used in the research – philosophical, theoretical, methodological, and contextual (Leavy, 2017); when mixing arts-based and mixed methods, the evaluation criteria necessarily need to integrate criteria that reflects the methodological approaches used in the study. Some example criteria could be identifying the usefulness for the community or context of the research, how voices were used or represented in the work, the role of the researcher and their relationships with participants (or co-researchers), and how the art evoked empathy, passion, and multiple meanings (Finley, 2003). Additionally, if a researcher provides a clear definition for ABMMR, this definition then indirectly identifies the criteria to evaluate that specific study, such as how the art and artistic practices were centered in the research process, how and when the art was integrated with other methodological approaches, and the researcher’s intentionality behind the art and integration strategies.

Conclusions

In this chapter, we outlined the similarities and differences between arts-based research, arts-informed research, and other arts-related approaches as well as between arts-informed mixed methods research (AIMMR) and arts-based mixed methods research (ABMMR). We showcased several examples of AIMMR and ABMMR in action and the reasons why researchers chose to integrate art and artistic practices with mixed methods. We also discussed the challenges facing educational researchers who use these approaches related to training, clarity of the methods or practices used, support for both the art/artistic practices and mixed methods elements in a study, clear terminology, and the philosophical tensions between arts-based research and MMR related to the overall aim of the research and evaluation. This chapter is intended to provide an introduction into the uses, benefits, and challenges to incorporating art and artistic practices in mixed methods studies in educational research.

Acknowledgment

The authors would like to thank Cherie D. Edwards for her feedback on an earlier draft of this chapter.

Qualitative research proposals primarily aim to excite readers about possibilities. Possibilities of new understandings about thorny, complex issues. Possibilities of justice for those long denied it. Possibilities of new insight into the many ways that humans live and believe. To be clear, qualitative proposals don't answer one's questions; the study does that. Proposals, rather, offer the possibilities of answers an academic field needs to know.

Exciting readers about a study's possibilities doesn't happen accidentally. Instead, planning a solid study and carefully writing to readers' interests generate that excitement—or at least their eventual approval of the proposal. In this chapter, then, I provide planning and writing advice for those hoping to develop a qualitative research proposal full of possibilities.

In this chapter I provide advice for writing qualitative research proposals, whether for your dissertation, a grant proposal, or any other purpose. My advice covers the things you should do before writing the proposal, like analyzing your audience, understanding what makes a qualitative proposal unique from other approaches, and some format concerns. I then discuss writing the proposal itself, including all the parts that make up a standard qualitative proposal—from title to conclusion and everything between. Finally I exhort readers to revise many times and seek feedback to make the proposal maximally clear, engaging, and persuasive.

One caveat for my advice: While I've got about 20 years' experience writing and reading qualitative proposals of all types, my way isn't the only way. (For instance, not everyone would accept my using contractions like *isn't*.) Your country, your institution, or your advisor may have specific traditions, rules, or preferences to follow. So in addition to considering my advice and the authors cited here, I urge you to speak directly with those who will review your proposal, which I say more about next.

Before starting writing

You must discover and keep in mind two things as you begin writing: (a) the audience for the proposal and (b) what that audience wants to know (Weaver-Hightower, 2019, Chapter 12). Naturally, many scholarly activities require proposals, including theses and dissertations, internal and external grants, published books, sabbaticals, evaluation projects, and human subjects and ethics reviews. Slightly different audiences read each of these, and readers' expectations stem from what you are asking for—permission to do the study, time off (or on), or funding to make it all happen. You must convince them that their time and treasure will be well spent on you. Yes, the quality of your ideas—their significance, potential implications, originality, and so on—ought to be the deciding factor, but don't overlook the necessity to tailor your proposal to speak to readers' needs and concerns. You can't please everyone's

tastes, but you can address why, for example, you've used a theorist you know one of your committee members hates, or you can carefully explain why you need money for in-person travel to a particular archive rather than just using their online catalog.

Sometimes you know your specific reader; sometimes you don't. For a dissertation proposal, you likely know most of your committee members and your advisor, so you might have a good sense of what they like, how they themselves write and research, and how they work with students. If you don't know a particular member that well—say, a member from outside the department or a replacement for a retired member—take them to a beverage-based meeting (you buy, or at least offer!) and get to know them. You might similarly know the people reading a sabbatical proposal, but get to know anyone you don't already, and explain what you're hoping to do before it comes to a vote.

For most grant proposals or ethics reviews, on the other hand, you are unlikely to know the readers in advance. You therefore can't write to their specific desires or avoid their pet peeves. You can, however, do your homework on what the organization wants from a proposal or what they have funded previously. Phone the grants officer and ask for advice. Most websites also now contain clear directions and winning proposal examples. Make sure to read such materials and follow directions exactly. If, for instance, the directions say your bio should be two pages, don't let even one line spill onto a third page.

You can also safely write to a "general audience" of scholars when writing a proposal for unknown readers. Assume that general audiences share three important characteristics: intelligence and curiosity, local knowledge, and significant skepticism when they read (Weaver-Hightower, 2019). For readers like that, write without "talking down" to them. No need to define *education* when used in a standard sense, but don't assume that everyone knows a specific philosopher's definition of education, either. General readers' local knowledge means you cannot assume they know about current events or the specifics of another country you researched. Better to write as if a general reader lives elsewhere, meaning that you'll have to explain things. Readers' skepticism, finally, requires you to defend your ideas and anticipate their "yes, buts" throughout. Scholars read analytically, against the grain, looking for alternative explanations. Make sure your proposal honors that by giving reasons and evidence for why your theoretical framework and methods will work best.

What makes a proposal truly qualitative?

Speaking of frameworks and methods, it behooves us to consider what makes a qualitative proposal particularly qualitative. Just doing interviews is not enough. Analyzing a handful of open-ended questions on an otherwise quantitative survey is not enough. Coding one's data is not enough. Doing a qualitative study and a proposal for it requires that you embark from a qualitative mindset with qualitative goals.

Maxwell (2013, Chapter 2) outlines a great set of qualitative mindset goals—"intellectual" rather than "practical" to emphasize that these are not the what-I-will-do-with-the-knowledge goals. In short, a study fits qualitative paradigms if it seeks to understand (a) the meanings participants hold about the events and objects around them, (b) the particular contexts participants face and how those influence events, and (c) the processes taking place. It also fits if the study intends to develop (d) ground-up theories for unanticipated phenomena and influences or (e) causal explanations about phenomena based on context or belief rather than, say, demographic categories. One distinguishes qualitative and quantitative studies based on "the distinction between thinking of the world in terms of variables and correlations," as a quantitative study does, versus "events and processes" on which qualitative studies focus (Maxwell, 2010: 477). It might seem like an obvious thing, but ensure that you are actually doing a qualitative study, with a mindset focused on beliefs, contexts, processes, and events, before you propose a qualitative study. If you're just borrowing a qualitative method or two, but your analysis has a quantitative focus, like code frequencies, correlating demographic factors, and so on—basically "quantitizing" your qualitatively collected data (e.g., Sandelowski et al., 2009)—you might reconsider calling your study "quantitative" or "mixed methods."

The format

Also ask your advisor or grant officers about the proposal format. Even though we currently enjoy a detente in the "paradigm wars" (Gage, 1989) and qualitative methodologists have established scores of uniquely qualitative approaches to valid research, quantitative research's dominance still burdens proposal formats for many grant applicants and graduate students. Nowhere is this truer than the dreaded first-three-chapters dissertation proposal. In many academic departments, tradition requires the proposal be the first three chapters of a five-chapter dissertation. The student writes the introductory chapter, including the problem statement, rationale for the study, and overview; a literature review chapter focused on all other studies that have investigated the topic; and a methods chapter, which lays out the exact procedures to be undertaken. This format works well for quantitative studies that simply require one to then implement their survey or their controlled experiment, write what statistics were generated in the fourth chapter, and discuss whether their hypothesis was confirmed and possibilities for why in the fifth chapter.

Though sensible for quantitative studies, in my experience the first-three-chapter proposal format usually works terribly for qualitative studies. It misunderstands qualitative research's nature. Qualitative research doesn't start from a hypothesis that one will simply confirm or reject. Sure, we have hunches about what we will find, but most will have those hunches blown to smithereens quite early in a study. Questions—even entire topics—emerge and change when qualitative researchers encounter the field's realities. One's proposal can hardly be expected to anticipate the literature that will illuminate those changes. Methods may have to shift, too, as new questions emerge and access to people and places shifts. The collision with reality thus creates two possible problems for those who have written a three-chapter proposal. They can either scrap most of their hard work on those chapters to reflect the actual study, or, if they leave the three chapters as is, they end up with a kind of schizophrenic study whose topic, literature, and

methods don't match their conclusions and themes. I get why people like the three-chapter format: it's comfortable and familiar, and they think, "Hey, you're more than halfway done with your dissertation when you propose!" It's just not true for high-quality qualitative research, though. Using that format adds extra work for qualitative researchers.

Obviously, I alone can't make your department shift its approach to proposals if they love the three-chapter model. Show this chapter to your advisor or the department chair, though, and see if you might do something more appropriate to qualitative research. I agree with [Maxwell \(2013: 127\)](#), who suggests a 5000-word (roughly 20 pages double-spaced) proposal works well for a qualitative study. In some countries, like the UK or some European countries, something more like 6 or 7 pages are preferred, but I personally would find it hard to be confident of the student's direction at so short a length. On the other end, I would suggest nothing over 40 pages, because then you're not focused enough, not investing the time and thought needed to be concise, or just showing off how much you've read! A singular, coherent prospectus with plenty of headings works better than "chapters" in so short a length. That length also provides plenty of room for the required information I suggest below, but it doesn't over-invest you in literatures and procedures that become irrelevant when your study design inevitably "emerges" in new directions.

A quick note on format for those considering an article-based dissertation, consisting of three or more "publishable" articles (if that is an option at your university). The proposal naturally needs to fit that unique kind of dissertation. Most of what I say in this chapter still applies, but you must describe the setup of all three (or four or however many) articles *individually*, including literature review, proposed research questions, methods, ethics, and so on. This might take much more word count than describing just one study. The article-based dissertation proposal also requires a section—perhaps two, one at the beginning and one at the end—that explains how the various articles relate to one another and how, together, they build toward contributing to a larger research problem. As with other approaches, ask your advisor for guidelines and examples of such proposals.

Writing it: what to include in your qualitative proposal

Whatever their limitations, first-three-chapter proposals include all the basic requirements for any proposal, including the 20- to 40-page dissertation proposal format I recommend: an introduction, a review of some related literature, and the intended methodology and procedures (see also [Marshall et al., 2022: 80](#)). In this section I discuss each of these general parts so that you know what to include.

First, though, let's review your proposal's two main goals: "convincing a supervisor and committee [or grant reviewer or editor] that the topic is worth researching and the candidate has the wherewithal to carry it out" ([Kilbourn, 2006: 529](#)). Those goals might sound simple, but meeting them requires telling readers key things in a coherent way, showing how your design elements interrelate seamlessly. Still, while easier said than done, keep those goals in mind as you decide what to include.

Don't treat the following as a fixed recipe, for any proposal must be tailored to the unique needs of the study. Nor do you have to compose in this order, start to finish; write sections as you feel prepared for them or as the ideas pop into your head. Your final proposal should probably present them in roughly this order, though—unless you have compelling reasons not to—because readers expect information to flow this way.

Beginnings

Go ahead, have an interesting title. Nothing too gimmicky nor obscure ([Wolcott, 2009: 123–124](#)), but your title can usually be more interesting at the proposal stage than at others. Your title creates your first impression, so make it the impression you want. Serious and grave? Engaging? Fun? Innovative? Your title conveys a great deal. This can include methodology, if a key aspect. [Creswell and Plano Clark \(2018: 146\)](#), for example, suggest explicitly including "mixed methods" in the title of any mixed methods study. I like doing this for any specialized qualitative approach (autoethnography, critical ethnography, transcendental phenomenology, and so on; many are covered in chapters in this volume), because it primes readers to assess the proposal with those approaches in mind. Also make sure the title conveys the study's qualitative nature; avoid "factors," "measuring," and other quantitative terms in favor of "beliefs" and "exploring." If you know the specificities of location and participants already, include those to avoid overgeneralization. For instance, "The Construction of Identity in Authors Theater: A Case Study of one Fourth Grade Classroom in the Midwest," is much better with the subtitle than without because it doesn't overpromise the amount of data and diversity you will have. Just do consider it a working title, subject to frequent change as your ideas evolve. Reflecting later on this titular evolution can provide insights into your project's development ([Peshkin, 1985](#)).

Once you get the title right (for right now), focus on the proposal's most important paragraph: the first. My best advice is get right to the point! Make the very first sentence plunge headlong into your topic or aim. Rather than trite gimmicks like "Merriam-Webster's dictionary defines ..." or burying readers in 200 years of history leading up to the topic, hit readers explicitly with the subject. Consider starting with a sentence like "The purpose of this study (chapter, monograph, article) is ..." ([Wolcott, 2009: 13](#)). Readers will be wondering this most urgently, so why not give it immediately? I'm decidedly not saying the opening has to be boring or clinical. Qualitative research gives you the opportunity to introduce observations and quotations, representative events from the field, quotes from participants, or piquing anecdotes that catapult readers into the topic. Just make such examples clearly related so that readers aren't still wondering what your subject is five, six, seven or more pages into your proposal.

Consider the following introduction to an example dissertation proposal:

Educators desperately need alternative methods of distributing and receiving professional development. Research reveals that “good professional development” should be designed around teacher interest, connected to teacher’s current knowledge, and supportive and nurturing of teachers’ intellectual capacity (Corcoran, 1995; Little, 1993). In other words, professional development should be learner-centered. However, providing “good professional development” for teachers is extremely challenging for local school districts. Teacher interest, knowledge, and intellectual capacity vary widely within and among schools. Offering appropriate professional development requires a large investment in time and money. This type of investment is often neither a priority nor a possibility. Therefore, despite research, school districts typically offer professional development opportunities that are irrelevant and uninteresting for. (Quoted in Maxwell, 2013: 181)

Key in on the first sentence. The topic, professional development, appears in the very first sentence, and in a prime position for emphasis—the sentence’s end. At a svelte 11 words, the sentence gets straight to the point with no flourishes. Teachers also “desperately” need professional development to be high quality, according to the author, establishing the importance and urgency right away. It’s not “stylish,” but this opening works well.

This sample introduction also highlights the next thing you need to accomplish: establishing the research problem. (If the word *problem* sounds like deficit thinking, replace it with *statement* or something more to your liking.) Clearly state what needs the reader’s attention, like inequitable educational outcomes for particular groups, an incorrect way of conceptualizing a phenomenon, or gaps in the field’s knowledge. For the sample above the problem is clear: professional development is “irrelevant and uninteresting,” and something “desperately” needs to be done about it. Make your own problem statement similarly clear and explicit. No beating around the bush or burying it under an avalanche of literature and jargon. Readers want to know your topic’s significance, not just to you and your advancement, but to everyone. As Kilbourn (2006) notes, a key challenge for the proposal writer involves “the need to construct an argument for doing the research in the first place.” Kilbourn also points out that the research should be based on “genuine inquiry” rather than seeking to prove what you already think—and readers can often tell if you’ve already made up your mind about the topic. Why do we—scholars, practitioners, or society in general—need to know the knowledge you plan to produce? What do we already know, and what are you adding to what we know? What usefulness does your study have? Not that it must have immediate application, but it should at least pique the curiosity of more than just you. (This is what a book publisher will be looking for in a prospectus, by the way, to get the all-important answer of “Who will buy this?” [Allen, 2016, Chapter 6].)

The middle, part I: setting up your design

The middle, overall, is the veggie patty in the qualitative proposal sandwich. It’s the “meat” between the beginning and the ending. Honestly, readers care most about this information. While the beginning establishes the problem and need for studying it, the middle—by far the longest part—establishes the study design. Of the two major questions—is this worth doing and are you the one to do it—the middle of the proposal best answers the latter. By discussing what has come before (theory and literature), what you’ll do to answer your new questions (methods), and the logistics (timelines and any budget), you give readers insight into your training, reasonableness, thoughtfulness, and skill.

For convenience I have separated the middle into two parts, the setup for the all-important design and then the design itself. This first section, the setup for your design, largely revolves around what others have said and done, including the literature review, the theoretical framework, and the methodology. You will do much citing of sources in this section, while in the design the focus shifts to your study plans.

Literature

What do we as a field know about the topic already, and what don’t we know? Those basic questions guide a literature review. It can be tempting to spend vast time and word count reviewing literature, particularly as reading and citing others often dominate graduate education and feedback from peers and professors. Resist the feeling that you must have read every article and book ever written on your topic. Don’t drown readers in a forty-page literature review, no matter how much you fear your committee are only testing how much you’ve read. I like how Vagle (2018) calls it a “partial review of the literature” (142). For a qualitative proposal, particularly the 20–40-page version I suggested, just spend a few pages reviewing the literature that supports what you anticipate right now, at the point of entering the field. You can also forecast other bodies of scholarly literature that may become important as you proceed and the design emerges.

For the literature you do include, focus on themes and broad strokes. Only focus at length on individual studies when they have influence, historical value, or close resemblances to your study. Few things bore readers more than the “furniture catalog” literature review (Haywood and Wragg, 1982), where the author summarizes one study after another with little attention to the relationships among studies. Writing instead about themes in the literature, citing the studies as groups or examples, shows that you have digested and synthesized the knowledge in the field rather than just having collected a bunch of studies from a keyword search. Be selective about what studies get put center stage in your proposal.

Make sure to also include studies that contradict your approach or beliefs—and as a reader I always assume some exist. Exploring and taking stands on disputes and tensions puts you in dialogue with others in your field, ultimately giving you an opportunity to advance knowledge by critically assessing the field’s knowledge base. Not only might readers already know of opposing studies and

wonder why you don't address the contradictions, but including them emphasizes your fair mindedness and honesty, another sign that you are the right person for the job ahead.

Theoretical framework

How will you approach theory? Do you have a particular theory you are trying to “test” in your qualitative research? Some researchers do. They apply, say, a model of culturally relevant pedagogy (e.g., [Ladson-Billings, 2021](#)) to their research site to see how the model does or doesn't explain the teaching going on there. Some turn their noses up at *a priori* theory in qualitative research, but I personally believe it has its place. No one really begins a study with a truly blank slate.

Some researchers, not dissimilarly, use the theory to “think with” ([Jackson and Mazzei, 2012](#)), meaning that a theory provides sensitizing concepts that frame their view of the research, a particular way of viewing a phenomenon. So something like New Literacy Studies, for example, views literacy as practices and events shaped by social context and relationships, rather than literacy as fixed in one's ability to decode language (e.g., [Barton et al., 2000](#)). That's not a theory to be tested, but a perspective that influences how one sees the world and sways one's approach to research design.

Of course, some qualitative researchers intend to create theory, such as through grounded theory approaches (e.g., [Charmaz, 2006](#); [Glaser and Strauss, 1967](#)). In these cases, relevant theory either doesn't exist, or the researcher believes that available theories are not adequate or plausible. Even if creating theory, you must still discuss your relationship to theory in your qualitative proposal. What theories have you considered, and why have you rejected them? Do any come close and just need to be tweaked? How will you go about constructing your own theory while sticking closely to participants' meanings and experiences?

Methodology

Speaking of theory, your qualitative proposal should address the intellectual traditions of knowledge production that guide your procedural choices—that is, your methodology. What general approach will you take (methodology) and what specific procedures (methods) will you use? How will you use “evidence and argument” ([Kilbourn, 2006](#)) to make claims about your topic?

Scores of specific methodological approaches huddle under the qualitative umbrella. [Creswell \(2013\)](#) has his classic five: ethnography, case study, phenomenology, grounded theory, and narrative research. Many more are available, like hermeneutics, discourse analysis, content analysis, ethnomethodology, life history, conversation analysis, portraiture, autoethnography, arts-based research, duoethnography, photovoice, task analysis, and poetic inquiry (many, again, covered in other chapters in this volume). You can even just choose “generic” ([Caelli et al., 2003](#)) or “pragmatic” qualitative research ([Savin-Baden and Major, 2013](#), Chapter 11) rather than struggling over which specialty fits. (In my experience, students tend to lose more sleep over which specialty they're doing than over their actual findings.) Regardless, each approach has its own perspective on what counts as evidence, how one collects and analyzes evidence, and even how one should write ([Weaver-Hightower, 2019](#), Chapter 11). Whatever your chosen methodology, describe for readers its basic tenets and views of the social world, the procedures typically involved, and cite the methodologists you rely on.

A quick caution: while increasingly acceptable to use “alternative” methodologies, both in conducting and representing qualitative research (autoethnographies, participatory methods, comics, theater, etc.), know your audience! Have they approved or funded work like this before? Are they knowledgeable about or open to non-traditional research? Not that you should compromise a design that fits your research questions, but know that extra steps and some convincing might be involved.

The middle, part II: your design

Experienced readers—and assume yours are—anticipate seeing certain sections in a qualitative design description, usually in the following order:

- Research question(s)
- Site(s) and/or participant(s)
- Data collection
- Data analysis
- Validity and reliability
- Ethics
- Logistics (timeline, budget, data management)

Include each in your proposal. Most of all, plan these elements out in as much detail as you possibly can.

“But wait,” you might be thinking, “qualitative designs must be emergent! You said so yourself.” Absolutely true. Qualitative proposals have an important contradiction at their heart: you must have a detailed plan even while knowing it will likely change considerably. That's why [Sandelowski and Barroso \(2003: 781\)](#) call qualitative proposals “exercises in imaginative rehearsal.” You must anticipate how your study might go, showing your expertise and willingness to adapt through your detailed design. No one wants to give you money or unleash you on participants if they think you will “wing it” in the field. They want to feel confident that you know enough to at least construct a plausible opening approach.

So how does one both plan in detail and plan for emergence? Plot the ideal approach but frequently use subtle statements like “My initial plan to analyze the data is to ...” or “Emerging evidence might suggest other means of ...” to indicate your awareness of

likely change. Explicitly convey to readers how qualitative designs, by their nature, must be open to emerging realities. Look at how [Sandelowski and Barroso \(2003\)](#) phrased it in their successful National Institute for Nursing Research grant:

As is the case with any qualitative project, the design will be emergent, or highly dependent on the ongoing results of this experimentation as the study progresses. Although we separate data collection, analysis, and interpretation here, the better to communicate our research plans, these processes typically proceed together and strongly influence each other in qualitative studies. Design dictates what the quantitative researcher will do; in contrast, what the qualitative researcher does determines the design. (796)

They then cite other studies that can guide them moving forward, even when the path is unclear. Citing other researchers and their decision processes convey to readers that your plan's gaps aren't anomalous or failings, but rather accepted means of working qualitatively.

So emergence cannot be an excuse not to plan. Even if you don't know yet, for example, how many participants you will interview, at least "explain the *basis* on which you'll make your decision" ([Maxwell, 2013](#): 125; emphasis original). That basis could be things like how many people respond to your recruiting, the richness of the data you're getting, or how many instructors use the practices you're studying. Explaining your thinking will give your audience certainty that you can confidently handle it when things inevitably change.

Research questions

Your research questions are vitally important. They also will likely change a good deal across your project. Because you will confront a reality that might not align with your expectations, some questions might need to change or might not be answerable at all. I myself had ten research questions for my dissertation proposal, but I was only able to answer six and a half of them. It is fine to start with broad questions, knowing that you'll winnow them down and sharpen them as your study progresses.

When composing your question or questions—and no one I know suggests more than three or four, much less ten!—make sure that each demonstrates six characteristics. Each question should (a) be concise, (b) ask a singular question, (c) have a qualitative purpose, (d) reflect your study population, (e) fit the theoretical or methodological orientation, and (f) avoid judgment, evaluation, and practical goals ([Weaver-Hightower, 2019](#): 175–176). Take for example two questions comparing qualitative approaches to the same topic:

Pragmatic qualitative research: What do online teachers see as the incentives and barriers of teaching online?
Grounded theory: What explains (how can we theorize) instructor online teaching behaviour? ([Savin-Baden and Major, 2013](#): 109)

Each asks only one question—though one might quibble over *incentives* and *barriers* creating separate questions in the first—and neither has superfluous words. Each is qualitative in that it examines social behavior and meanings. Each reflects its methodology's tenets, as explicitly labeled. Even though the first is "pragmatic," it doesn't seek to judge or evaluate an existing program, just to solicit what participants believe. Finally, these questions don't name a specific site or participants, but in a proposal you don't always know this information yet. If you do know that information, rephrase these with something like "What do online teachers at Eastern Seaboard University see as the incentives and barriers of teaching online?"

Sites and/or participants

Speaking of your study site and participants, describe these if you know them, or describe how you will determine these after the study or grant gains approval. Provide a rationale for your sites and participants; why can they, particularly, answer your research questions? Explain any reasons for excluding some participants, like only wanting a certain age group or geographic region, say.

Once you have explained why your participants are the right ones, explain how you will (or already did) find them and secure their participation, both at the beginning and throughout the study. Such issues should include any planned recruiting efforts, how you will negotiate entry, how you intend to gain and maintain trust, your role (participant, observer, reciprocity agreements, etc.), and plans for exiting the site responsibly.

Data collection

Data collection (or *generation*, if you prefer; e.g., [Garnham, 2008](#))—alongside data analysis, discussed in the next section—will likely receive the most scrutiny from readers. These provide a sense of how well you understand the topic, the research process, how humans behave, ethics, and how to solicit knowledge. If you propose to collect data you can't access qualitatively—say, how something happens in the brain—or suggest that participants will unflinchingly answer questions that are deeply private or embarrassing, readers will doubt your abilities. So first make sure that you can get the data you need, particularly that your data collection methods match your research questions.

It might just be my personal bias, but I tend to be most skeptical of projects that solely interview participants. Certainly some questions researchers can best answer with interviews, like constructing life histories (e.g., [Seidman, 2006](#)), and many methodologists have well developed methods for interviewing (e.g., [Roulston, 2010](#)). Many, many research questions, though, could be

answered much better by including other methods, as well. I suspect that interviews seem easiest, whether logistically or analytically, because of the directness of asking a question and getting an answer straight from participants. Interviews can be complex and raise many concerns, though (see, e.g., chapters in [Holstein and Gubrium, 2003](#)). Interviews may certainly tell you what participants believe explicitly—or, at least what they will share with an outsider—but interviews may not be as insightful about processes and behaviors.

If your research questions ask about processes and behaviors, consider observation, whether as participant or not. Consider collecting artifacts, as well, including texts participants create or use, media, art, and so on. These have meanings one can glean from how, when, where, and why people use them. My point is simply that observational, textual, and artifactual data can be as or more useful than interviewing, and some readers will wonder why you don't include them if your research questions suggest them. Don't forget, too, that these other methods can be used in combination with interviewing to create more integrated, trustworthy findings—a form of methodological triangulation ([Denzin, 1970](#), Chapter 12).

As with other methods sections, make sure your data collection description includes significant detail. If you plan to conduct interviews, include at least some sample questions to show readers you'll ask the right things. How many participants will you interview, for how long, how many times, and how long between? Will interview questions vary by participants, say by age or role? If you're observing, specify what kinds of events you'll observe. What will you be looking for and how will you know it when you see it? The latter can be quite important, as concepts like *motivation*, *relationship*, or *emotion* can be difficult to spot. Just as with interviews, how many observations will you conduct, how many times, for how long, and how long between? If you are working with artifacts, like documents, where will you find them, how will you get permission to have them, how many do you need, and so on? Again, readers will generally understand that details are hard to know in advance and are subject to change, but giving these details shows you have thought your project through and can anticipate both changes and their bases.

Data analysis

In my experience, qualitative proposal writers fall down most often on describing data analysis. Many data analysis processes—given qualitative research's nature, largely cognitive processes—can be challenging to describe even when researchers have already done them. Indeed, most writers struggle to get any more specific than “themes emerged” ([Dickie, 2003](#); [Humble and Radina, 2019](#)). To be fair, most quantitative researchers couldn't explain how their statistical tests work; they just report what the computer spits out. Anticipating precisely how you will analyze data before collecting any and when you expect your design to change can sound fantastical to many qualitative researchers, particularly novices who might never have done a large-scale analysis.

Solutions are available, though. First, look at how methodologists in your chosen qualitative approach suggest analyzing data. Perhaps, for example, you like [Moustakas' \(1994\)](#) approach to phenomenology; outline his specific analysis steps and suggest how your data will likely fit them. If you have some sample data—perhaps from a pilot study—consider demonstrating the process. Second, look at other authors' data analysis strategies in their published work. If you are enamored with [Strauss and Corbin's \(1990\)](#) axial coding process, for example, look at how researchers like [Morrow and Smith \(1995\)](#) implemented it, and imagine your data being analyzed in that way. Third, qualitative researchers have access to many inclusive, cross-approach means of analysis and coding ([Miles et al., 2014](#); [Saldaña, 2021](#)). Here, too, imagine the data you'll have and project how you might make connections between your data and the research questions. On this last point about matching the data with research questions, I have often found it helpful, both for planning and for communicating with readers, to create a table with the research questions in one column and the data sources used to answer each in another column.

Making a table of data–research question correspondences can also help ensure you've accomplished another key task: accounting for all the data sources you propose to collect. If you have, for example, said that you plan on doing ten observations of a classroom in addition to interviews with four teachers, don't only describe analyzing the interviews. Readers will rightly wonder why you're doing the observations if you overlook analysis of them.

Some might wonder about the role of data analysis software in a qualitative proposal. I don't suggest writing much about it at the proposal stage, honestly. After all, most qualitative software has similar features and uses, and rather than doing the analysis for you like statistics packages do, they mostly just manage data. If you do discuss software, name it and describe how you'll use (or perhaps overcome) its features to fit your unique data and analysis processes. As [Woolf and Silver \(2018\)](#) rightly note, one has to “translate” the emergent processes of qualitative research into the cut-and-dried operations of software. If you aren't at this point yet, though, don't feel the need to even mention software.

Again, crafting the details of an emergent process can prove challenging, but embrace the challenge. To do less, to essentially say “I'll figure it out once the data is collected,” risks readers thinking that you don't understand qualitative research or that you'll waste your participants' time and good will or waste your grantor's money, all without getting valid results.

Validity and reliability

While data analysis gets discussed poorly in qualitative proposals, validity and reliability—*trustworthiness* ([Lincoln and Guba, 1985](#)) or *quality criteria* ([Tracy, 2010](#)) or myriad other terms for good work, if you prefer—often don't get mentioned at all. Or, too often, just the names of procedures are tossed around as if such “boilerplate” lists are “magic charms that are intended to drive away evil” ([Maxwell, 2013](#): 123). Just do the technique and you've checked the box. Presto! Validity accomplished. That too—common view fundamentally misunderstands validity. As [Maxwell's \(2013\)](#) chapter title succinctly puts it, validity seeks to answer “How might you be wrong?” You can't rule out being wrong with lists of techniques; you rule it out by the evidence techniques generate (121).

Proposal readers want details of your validity and reliability plans, just as they do with other sections. Regarding reliability, how might you use multiple coders and establish interrater reliability (e.g., [Hruschka et al., 2004](#)), if applicable? How might you coordinate teams of researchers to ensure they keep their focus and interpretations mostly aligned? Regarding validity, which of the common techniques of trustworthiness—such as member checking, triangulation, peer debriefing, prolonged engagement, negative case analysis, and more ([Lincoln and Guba, 1985](#))—would effectively double check that your analysis really answers your research questions? Consider adding a third column to the table of research questions and data sources suggested above, this time including the procedures and evidence you might use to assert the validity of each question's answer.

Ethics

Discuss your study's ethics—the right and wrong of how you'll treat participants—and don't be dismissive of your responsibilities by only relying on Institutional Review Board (IRB) approval or suggesting that nothing could possibly go wrong. I've never been part of a study, even as a committee member, that didn't have an ethical dilemma arise—usually small but sometimes large. Discuss the ethical problems you can anticipate (or have confronted already while planning the project) and how you might manage dilemmas you can't anticipate.

Though I can't cover every ethical situation that could arise, some questions are frequent. Consider how your presence might impact the people and places you conduct research with. Are you too close to the participants already? Are some of them particularly vulnerable? Could your research uncover things they wouldn't want you to know or share? Might you endanger them, their reputations, or their livelihoods? How might you handle power imbalances? Could any confusions arise about your role in the setting? Do you have conflicts of interest that might make you unable to be honest? What cultural misunderstandings or tensions might you have to work through? Will anyone not directly participating be affected by your study? How might you write about participants in ways that are respectful and fair? All researchers face questions like these. No one can remove all ethical challenges, but they can be honest about them and put in place techniques to check biases, like reflective memoing, peer review, and debriefing sessions.

Delimitations: what are you not doing?

You can't do everything in any single study. Leave some questions for your second and third books! Make sure to tell readers what you are not doing in your study, your delimitations or boundaries. You might be researching the behavior of Egyptian students at school, for example, but for various reasons, despite its potential value, you won't be watching their behavior at home because access would be too difficult. Maybe you're studying new professors' teaching, but you're not going to include anyone from the college of education because they usually have teaching experience already. In your proposal, make it clear what you are doing, but make it just as clear what you won't do and why. Drawing boundaries around what is and isn't your project and providing a rationale make you look thoughtful and purposeful. Ignoring such discussion makes you look forgetful or capricious.

Pilot studies and previous data (if any)

Let readers know what you have done on the project already. If you did a pilot study, briefly overview what you did that relates to the current study. You don't have to spend pages and pages of your proposal explaining the pilot study's every detail. Just include a few paragraphs about what you learned and tried in the pilot and what you plan to change in the proposed research as a result.

Also mention if you have already begun working on the current project. Have you contacted some of the gatekeepers? Have you enrolled participants? Do you have IRB approval? Are you planning on reusing some previously collected data? If your proposal is for a dissertation, disclosing previous work to your committee is critical because they may want to view any material already collected to ensure that it meets standards.

Researcher disclosures

In qualitative studies, researchers are the "instruments of the research" (e.g., [Lincoln and Guba, 1985](#): 192–195); their cognition and emotions filter what they see, hear, and interpret. Thus readers need to know about you and how you will perform as that instrument. Who are you, and what experiences do you bring that will shape your views? What biases might you bring? What reactivity might you provoke in the field with participants? Why are you, particularly, equipped to do this?

In this section of your proposal, explore your subjectivities, biases, training, and expertise. Disclose demographics that could reasonably be assumed to relate directly to your study. If your project focuses on race, for example, share yours and how that might influence you. The same goes for identities like sexuality, gender, social class, disabilities, and so on. If you hold political, religious, or moral stances that might influence how you think about the people and topic, confess to it. Talk about how you have prepared for your research. If you have taken doctoral courses on the topic, trained in advanced methods, published in the area already, or worked on related grants, let readers know. They will have more confidence that you can successfully complete the study.

Though often focused on checking biases, a disclosures section is not meant to be all negative. Consider positives that might result from your subjectivity, too. Might being a man, for example, give you privileged access to the group of boys you want to study? Might you understand your study of first year teachers better from having spent the last few years supervising student teachers? Don't oversell your identities as making things surefire or easy, but be thoughtful about the advantages you might have.

Use your section on researcher disclosures for developing methods, as well. How will you prevent any biases from skewing your interpretations? What insights can you only get because of who you are? [Maxwell \(2013\)](#) suggests memoing about your researcher identity. Debriefing with peers or supervisors can keep you honest and sensitive, too. It's OK to have identities and stances; you are

human, after all. It's not OK to hide these or pretend that they don't matter. Share your plan for keeping them in check or capitalizing on them.

Logistics

You can also show your skill and thoughtfulness—in other words, that you can accomplish the study—by providing a realistic timeline, budget, data management plan, possible “deliverables” for a grant, and, for a dissertation or book proposal, a tentative outline of chapters.

What steps will you take and how long will it take you to do them? Breaking down the parts of the study and crafting a timeline tests your ability to be realistic. Grant agencies are more likely to hold you to this timeline than are dissertation committees, but whichever you're writing, give yourself ample time to collect enough data, think through it all, and then write the study up in an engaging and coherent way. It amazes me how many students think they'll do ambitious fieldwork in a semester and then write and defend a dissertation in a semester. Those who actually accomplish such feats are as rare as mega-million lottery winners. High-quality qualitative research takes time, frequently faces obstacles (the “emergent” part!), and doesn't enjoy the straightforward writing templates that other methods might. Tamp down your hunger to finish your degree or get that tenure-assuring project done, and plan in extra time for every stage. One great approach involves creating a table listing in detail your study's phases or steps, and give a tentative completion date beside each. And by detail I don't mean a step as broad as “data collection”; I mean breaking large phases like that into individual tasks, like “Complete first set of observations in all schools,” or “Interview first five principals.” Such detail quickly exposes places where your timeline might be too aggressive.

If you are asking for money, tell readers what it's for in as much detail as possible, and focus your ask on how that money forwards the project (rather than your career or your convenience). Don't be overly frugal (“I'll get all my supplies from the dollar store!”), but don't be extravagant, either. Outline your professional needs and give a solid rationale. Seek help early and often from people who are good with budgets if you're not.

Endings

Goodall (2008), writing about narrative research projects, calls endings “the pay off.” I think that description works well for proposals in any research approach. Give readers a sense of closure when you write your conclusion. No new information! Only give, reminders of what they have learned already in the proposal. Remind them, after that long trip through your detailed research design, that your project has important potential implications for policy, practice, research, and/or theory. Reinforce that your literature review suggests the need for your study. Emphasize that your chosen theoretical framework and the methodology and methods you proposed make it doable. Such summarizing helps readers see the whole sweep of the project in one concise package. The repetition of the information also helps them remember it. My motto for conclusions is “Leave 'em informed! Repeat, repeat.”

Too often I feel writers rush their conclusions, so they don't get all the “pay off” that conclusions make possible. Perhaps they are tired of writing by that point. Perhaps the deadline is at hand. Perhaps they just don't know what tone to set, so they simply stop at the end of the research design. Hopefully you won't fall prey to such temptations or bad habits, though. A strong ending can leave your reader feeling satisfied and confident, and that mental state bodes well for gaining approval for your proposal. To write your own ending, look for examples you like, get others to read yours, and revise frequently.

Revise, revise, share, revise, share, revise

My final bit of new advice concerns making your prose great—or at least better. Few writers can crank out perfect sentences and paragraphs, with style and concision and coherence, on the first try. Many attempt the one-shot composition, but few succeed. Many also—let's admit it—don't bother trying to make their writing clear or stylish, particularly in the sciences and social sciences. As Becker (2008) notes, writers in these fields get away with bad writing all the time. They confuse complicated, jargon-filled prose for smart ideas. Maybe they just know so much about the topic that they forget how to write well (Warren et al., 2021). In a proposal, though, writing well—clearly, concisely, grammatically, and with detail—brings pronounced advantages. Doing so enhances your image as someone capable of doing the work. I mean, if you can't be bothered to at least correct the misspellings your word processor points out for you, why would I trust you to research carefully?

The path to good writing goes through revision, and lots of it. Read your proposal over and over, making changes to make your ideas and words clearer. Take out unnecessary words that slow readers down. Explain potentially unfamiliar concepts. Add details and examples. Revision relies on many processes, which I detail at length in *How to Write Qualitative Research* (Weaver-Hightower, 2019), but make sure to leave sufficient time to do the many “waves” of revision I suggest. Revision should take longer than the first draft!

Also leave time for the “share” parts of this section's title. Receiving feedback as you develop the proposal and before you submit it is to your advantage. Get multiple rounds of feedback from your advisor, your peers, your colleagues—heck, from your grandma—and make sure to revise based on that feedback before the next round of readers. The more you give real readers an opportunity to catch mistakes, ask questions, and make suggestions, the more likely your proposal will be clear and compelling to the final readers who decide your fate.

Conclusion

I hope that this chapter, as I said of proposals writ large at the beginning, excites you about the possibilities for your own proposal. Yes, proposals are complex documents that take time to construct and refine, but they are not inscrutable. Identify your readers and what they need to know. Find out from those readers what format they expect, then follow it explicitly. Write an interesting descriptive title and make the opening hook readers by engage the topic right away. Review the relevant literature, but keep it a partial review given that new topics might arise as your study evolves. Then lay out your research design in as much detail as possible, including your larger methodological approach, your research questions, sites and participants, data collection strategies, data analysis approach, validity and reliability plans, ethics considerations, and reasonable logistics about timelines, budgets, and so on. Put a satisfying ending on it. Then—*voilà!*—your proposal is complete. All you have to do then is multiple rounds of revisions and sharing to make sure that readers recognize the brilliance of your ideas and the promise of your study. Naturally all of that is easier said than done.

The doing now lies before you. Take comfort from the knowledge that thousands upon thousands of scholars have written successful qualitative proposals; they have found a way through and you will, too. Hopefully, with my advice throughout this chapter, the way will be at least a little clearer. Good luck on your proposal!

Writing up qualitative research and inquiry can be difficult. We write to communicate but we also learn a lot during the writing process. Qualitative research is a large, diverse, and growing family of research approaches (Denzin and Lincoln, 2017). These many approaches draw on different western and Indigenous epistemologies, may or may not seek to be scientific, are applied for different purposes, serve the knowledge needs of different audiences, and must maintain ethical standards. These qualitative approaches may apply any of over 100 named methods or generate new ones to fit specific knowledge needs, and must persuade readers that the study's analysis, conclusions, and any recommendations are consistent with and limited to the study's delivered methods. Often the data generated by a study may require much more space to communicate in depth than is afforded in the 20-page manuscript limit set by many journals. Some forms of qualitative inquiry take the form of "hung" photographic exhibits, of creatively altered books, of spoken plays, and of autobiographical stories. Yet all are important parts of the large qualitative research community. Writing up qualitative research draws on and integrates many sources.

Of course, we do not write for ourselves. We write to inform, or to inspire, to bear witness, or to motivate others. These other people are our unseen and unknown audiences. Students, even at Ph.D. level, often have difficulty imagining that others will actually read their work. As researchers, we seek to learn, understand, and innovate. As qualitative research writers, we re-shape the processes of our own learning and find the best ways to inform others about what we have done and learned. Rarely is it best to simply restate our personal learning paths to get ideas across to others. Wolcott (2009) describes what we produce as a monologue. Readers do not tell authors why they chose to read this work, where to begin, or what parts are puzzling. As writers, we must imagine our readers and speak to them. We must inform our readers. Authors monopolize the conversation. Authors have to imagine an audience and then convince them that we know what we are talking about. It's not easy.

Across disciplines and professions, authors of qualitative manuscripts frequently report that their works have been unfairly turned down by journal reviewers (Pratt, 2009). These authors, among which I included myself, sometime believe that their work has been "slammed" by reviewers who are not knowledgeable about qualitative approaches and methods, or who have applied inappropriate standards in their reviews. It is also true that we have failed to reach, and to adequately educate, this crucial audience. I believe such hostile reviews are the result of the minimal way in which qualitative approaches and methods are taught and mentored at graduate level in most disciplines and professions. This is further compounded by a lack of consensus standards for reviews fitting the author's chosen approach. In my profession—social work—I found that qualitative research is most often taught in the United States at master's level in only one class session, usually squeezed between sampling and statistics (Drisko, 2008). No assignments asking for active involvement in qualitative research are found. At doctoral level, the typical Ph.D. program includes just one course in qualitative research. These are either an overview course or a course in a single named approach (Drisko et al., 2015). Minimally taught and mentored, many able students are simply not educated adequately to become expert qualitative researchers. For example, Emmons and Moravcsik (2020) view inadequate education in qualitative research as a current disciplinary crisis within political science. Similarly, there are few reviewers with extensive and varied training, wide-ranging qualitative research experience, and methodological expertise in qualitative research across professions. Qualitative audiences may have to be taught core research approaches as we report our research results (Stenius et al., 2017). We have to up our game.

Getting started

Getting started in writing up qualitative research can be a challenge for newcomers and veteran writers alike. The good news is that even false starts create fodder for later edits—once they are written! Common concerns are the pressure to write and the shame or guilt that emerges when we are not writing. The most useful response is to sit and write: a title, a statement of purpose, an

outline, ideas about what you want to study, or ideas about what you do *not* want to study. Clarifying the topic and delimiting what the study will include can be terrific starting points. Get going; put pen to paper or click those keys. Of course, it won't be perfect at first. But it's a start!

Having a steady base helps one be an effective academic writer (Sword, 2017). Sword studied qualitatively 100 academics and found that behavioral, artisanal, social, and emotional factors and habits each strongly impact writing output. By rating one's own comfort on each factor, one can identify how to build greater support and comfort in writing. Habits on these four dimensions evolve over time and change in prominence. Both developing writing rituals and letting them go can enhance one's writing. As qualitative writers we differ both one from another and we each evolve over time and experience. Yet we can increase our comfort and output. Experienced qualitative authors review and reflect upon how, when, and where they write.

In leading professional writing seminars, I often ask people *when* during the day they write most successfully. Many of us have a time of day in which we are most academically productive. Try to protect these times and write. I also ask *where* one writes. After laughter about famous writers' rooms and desks, it turns out we favor a wide range of locations and settings: indoors, outdoors, in tiny carrels, or in coffee shops, with noise, or in quiet. Some of us use outlines, others do not. The most interesting question was to what do you like to read? Response ranged from novels, to religious matter, to poetry, and on to graphic novels. Academic articles were never mentioned. Knowing what impacts your productivity can help you learn about why, and how, good writing 'works.' Identifying and respecting the conditions that help you write efficiently can save time and create comfort. Each writer is unique. Self-reflection on one's qualitative writing is important.

For those who use outlines, a detailed outline is a great way to start. Kellogg (1988) found that both written and "mental" outlining led to higher quality final documents and reduced attention overload. Outlines allow researchers to delimit what will be in the piece, and what will not. This information is vital for finding participants, and for informing colleagues, committees, and institutional review boards. Using a named research approach, having expertise and experience in data collection and data analysis, and planning out how to use 20 pages of double spaced text focus and guide our qualitative writing. The outline helps us to work in parts or steps, section by section. This allows us to focus in depth on one part of the work. Inevitably, how the sections integrate may need revision or expansion as the work progresses. Some material may prove unimportant and warrants removal. Working section by section can also help identify progress.

For those who do not use outlines, free writing may be a useful technique (Becker, 1986). Just write, with no changes or edits, for 10 minutes. Just let go. This is a great technique for exploring your own reactions in qualitative research and to set down for review what you notice, question, and doubt. If writing reflects thinking, then writing an introduction or a study overview gets us started in both realms. Set a timeline. Review the draft a day later and look for ways to improve its clarity and its organization. What works? What's missing? Are key terms defined? Is there a flow, a clear organization, developing? Does the writing have "grab" to draw in readers (Gilgun, 2005)? One can build incrementally on such a small start with additional sessions of free writing. These are directed to specific sections of the developing manuscript. As always, edits and reorganization will likely be needed as the manuscript expands. As Wolcott (2009) states "Until you have a rough draft of what you have to report, there is no chance of improving it" (p. 162). Of course, you also have no way to get detailed feedback from others unless they can sit with, read, consider, and respond to a written draft. Starting qualitative writing may be challenging but it is a vital first step. And—it builds confidence.

As the draft is edited and refined, qualitative researchers must look carefully for the internal consistency of the overall, enacted, research approach (e.g., grounded theory, phenomenology). How the approach, epistemology, data collection and data analysis methods fit together become key areas for review and consideration. Quality of content and clarity of delivery are both key.

Forms, formats, purposes and standards

Qualitative research and inquiry are presented and published in a wide range of forms and formats. Several recent developments expand on the traditional text-based qualitative report. Standards for such evolving works are not yet fixed: there are neither consensus guidelines for qualitative researchers across approaches, nor across disciplines and professions. Those guidelines that have been developed have been heavily questioned and critiqued. They often do not fit well with some qualitative research approaches (Kross and Giust, 2019). Qualitative inquiry using approaches like autoethnography and performance methods are not compatible with many Realist/Post-positivist oriented guidelines and publications standards (Drisko, 2013). There are, however, some general criteria for what makes a strong text-based qualitative study.

Recently developed methods—qualitative inquiry

While the focus of this chapter is on writing up qualitative research, several forms of qualitative research and inquiry are presented in forms other than text. Further, not all inquiry seeks to be scientific, and some qualitative approaches purposefully emphasize the aesthetic aspects of communication. Several recently developed methods (e.g., participatory action research, performance inquiry) seek to empower others, to democratize knowledge production, to broaden the ways in which qualitative research is presented, and to expand how it is evaluated. As an example, photovoice is a method in which "participants" are given cameras by researchers to document a (usually) researcher defined aspect of life about which participants are knowledgeable (Wang and Burris, 1997). One well known photovoice study documented the lives of the homeless through framed pictures with short captions. The study was "hung" in public settings such as libraries with the purpose of helping housed folks to better understand the experiences of the

homeless. The presentation's location was chosen to provide access to likely "consumers" of the study in an easily accessible public setting. While building public understanding and reducing stigma may have been a key research goal, the aesthetic dimensions of the presentations also impact how it is viewed and understood.

Similarly, "performance pieces" are short spoken or acted plays that *show* the audience the message, linking words with inflections, feelings, tones, and structures that engage the audience and shape understanding of the material (Gergen and Gergen, 2011; Haseman, 2006). Human interactions may also be viewed as performance (Denzin, 2001). There may be a complete or near complete text from which the performance is generated, but the presentations are embodied, enacted, live, and are not mainly intended as text. Here too aesthetic aspects of the performance both convey its message and link to everyday ways of taking in new information. Each of these qualitative research approaches may also be designed to shift consumer's attention: to shift attitudes or perspectives, to make viewers uncomfortable, to make the familiar seem unfamiliar. For example, the *Performance Research* journal offers a "dynamic space of performance that produces inspiring conversations, unlikely connections, and curious confluences" (2020, para 1). Guinier and Smith (2001) also argue that artistic performance may be used to influence others and to highlight power dynamics. Here research and the arts intersect and show mutual influence. Criteria for the "success" of such qualitative work may not be consistent with some journal reporting standards.

Autoethnography is another innovative form and format in which a researcher composed story links intimate personal experiences and observations to the social structures in which these experiences occur (Goldschmidt, 1977). The structure and design of the story, its aesthetic dimensions, are vital to its impact and success at informing and moving the consumer (Bochner and Ellis, 2016). As personal stories, authenticity is required, voice can be direct and strong, the imperfections of our understandings of others is side-stepped, and the legitimacy of telling one's own story is affirmed. Evaluative standards for these recent innovations in research approach have yet to be established, and may emphasize the artistic and aesthetic over the scientific.

Text based reports

Traditional forms of text based qualitative research have no required format other than the expectations set by researchers, journals, and committees. Different approaches to qualitative research will, however, also require specific sets of information to orient and guide the reader. Some of these methods and related terminology are specific to named research approaches. Write ups must inform the reader/consumer about what was done and how it was completed. Authors must guide the reader through the research and show what has been done and found.

A clear statement of the study question is a typical place to start (Drisko, 1997, 2013). All good research starts with a question of merit and worth. What will be studied, what it adds to knowledge, and its practical implications should all be mapped out briefly. It may be the case that the research centers on exploration of unknown territory, yet still a focusing question or topic is vital. The question orients researchers and readers alike.

Next, state the epistemology that orients the study (Drisko, 2013). Many qualitative publications fail to state their epistemological premises, forcing the reader to guess what is intended. Epistemologies have implications that may lead to omissions or inconsistencies in later stages of the report. For example, a constructivist study drawing on a convenience sample of 12 may close with recommendations and generalizations that would be more appropriate to a realist approach and a larger and more varied probability sample. The ways of knowing that orient a study should be understood by the researcher, clearly stated, and linked to appropriate and limited knowledge claims.

The researcher should also be clear about the intended audience of the report. Forms of writing often differ when created for the public or a specific group rather than other professionals from the same discipline. Again, focusing on an intended audience helps focus the researcher and the writing up of the report.

Ethical issues arise in most qualitative research with human participants. All research reports involving newly collected data from people should include a statement about providing informed consent and other ethical issues. Such a statement may be a short sentence. For example, "after review and approval of the study questions and approach by the XXX institutional review board ..." shows appropriate professional conduct and that the author has taken steps to consider and to protect human research participants. There are study questions that may be challenging for institutional review boards (IRBs) (i.e., the tea room trade study; some studies of drug use). It is also true that IRBs may not fully understand some forms of qualitative research (Van Den Hoonaard, 2002). A clear description of the study purposes and methods—whatever they are—helps inform and often to educate IRB members and readers alike. The participants in our qualitative research deserve our care and protection, which should be stated in all publications (Drisko, 2013; Lahman, 2018).

Doing qualitative research may also generate personal ethical challenges that are not often addressed by biomedical ethics models (van den Hoonaard and van den Hoonaard, 2013). These ethical challenges may also be unfamiliar to many ethics review boards (van den Hoonaard, 2002). Many such differences exist for qualitative researchers: The process of entering existing human groups and settings, making choices about payment or other incentives, staying in and participating within groups over time (or not), and in leave taking, can each pose interpersonal and potentially ethical challenges (Wolcott, 2002). Including diverse participants may raise the issue of "othering" (Lahman, 2018) while the depth of our information needs may also raise the issue of intrusion. How to ask difficult questions of vulnerable populations requires self-reflection and thoughtfulness. Asking difficult questions requires ongoing attention to the interests and experience of the participant. Such ethical and practical concerns should be explored in the published report, and may generate new questions for additional research.

Approaches and methods/techniques

Unfortunately, too many qualitative reports offer minimal detail on their approaches and methods. The term “approach” is used here to indicate a named qualitative research model, such as phenomenology, ethnography, or grounded theory. Qualitative research approaches may specify sampling methods or data collection methods, but all specify—to some level of detail—the research methods to be employed and how they jointly build knowledge. Sampling, data collection, and data analysis should be consistent with the selected epistemological premises of the study. That is, the overall study approach should be internally consistent with the study epistemology. For example, open, discriminate, and selective sampling should be reported in a realist premised grounded theory study drawing on [Glaser and Strauss’ \(1967\)](#) approach.

Methods section in qualitative reports need not be long but should address several topics. Is the sampling plan and its rationale clearly stated? Will the plan include possibly contradictory cases or evidence? Are the data collection methods clearly stated and consistent with any named research approach and methods? Is the method of data analysis consistent with any named research approach and methods? Are codes, themes, and interpretations clearly linked to reader available data? (Beware of reports that only offer a few sound bites summarizing complex coding processes!) Are the data and analysis credible? Is it clear how the researchers applied codes to varied material? Confirmable or disconfirmable? Meaningful in context? Saturated and complete? How is contradictory data understood? Are any claim of transferability or generalization consistent with the study epistemology, sample, reported data, and analysis ([Drisko, 2013](#))? The goal of the writer is to explain to the reader how the study was done. This is essential to establishing the credibility and verisimilitude of the study. A clear statement of methods helps to persuade the reader that the results of the work are meaningful.

Good qualitative studies also require a statement of the author’s personal location and pre-existing views about the topic. This gives the consumer an insight into the author’s potential biases and interests, supporting critical thinking by the reader. Such statements can also clarify the researcher’s intentions and assumptions. Reflection on the topic, the study, and one’s changing views each may help the reader understand the report more fully. [Stenius et al. \(2017\)](#) point out that each of these quality criteria also serve as reasons that qualitative manuscripts may not accepted for publication by journal referees or jurors. [Drisko \(2005\)](#) and [Pratt \(2009\)](#) note that even well described methods may be misunderstood or incorrectly portrayed by journal reviewers. Care in ensuring rigorous manuscripts is vital to their acceptance and publication. Clear explanations of methods may educate both reviewers and future readers.

[Humphrey and Simpson \(2012\)](#) argue that writing up collected qualitative data builds confidence and demonstrates beginning mastery. They call completion of a qualitative data analysis a “threshold” step in becoming an academic writer. Humphrey and Simpson call for attention to writing up qualitative data as promoting independent and autonomous research writing skills. They note that feeling “stuck” is a common, almost routine, step in becoming a qualitative researcher and writer. Instructors, mentors, and peers all can contribute to becoming unstuck and helping the researcher in “taking control of the thesis as a textual synthesis of data, theory” (p. 744).

Writing up qualitative research may be difficult, but it is vital to communicating ideas, methods, and results to others. Researchers often identify new results and implications as they work to create a cohesive and complete report: qualitative research is an iterative or cyclical process of thinking, planning, collecting data, analyzing data, and writing. Different parts of a project may be configured or re-configured differently to better impact selected audiences, and to address different information needs and learning styles. Providing a “road map” for readers that show how the study was conceptualized and completed is vital.

Quality checklists and guidelines

Academics, professional organizations, and commercial publishers have developed several formats and checklists to promote quality in qualitative research. These generally reflect an effort to establish scientific principles for the conduct of qualitative research. They also tend to be heavily and solely premised on post-positivist or realist epistemologies. Further, most tend to minimize the role of researcher self-reflection and reflexivity, seeking an objective account. [Calderón Gómez](#) argues that

The “scientific format” required by the majority of journals determines the representation of the research process by fragmenting it and reducing it to previously designed spaces. Similarly, the author is often asked to use an impersonal linguistic style that does not represent his or her involvement in the research process.

[Gómez and Carlos \(2009, para 34\).](#)

Given the growing diversity of purposes, audiences, approaches, and methods within qualitative research and inquiry, it is unclear if these formats fully and usefully reflect writing in today’s qualitative research landscape ([Barbour, 2001](#)).

On the other hand, checklists can provide some guidance for researchers, students, and educators. They show, in detail, expectations for realist qualitative studies ([Turk and Kalarchian, 2014](#)). They may not, however, include all components of a qualitative study deemed important to the participants, researchers, or future readers. The formats also point to content for educational curricula in qualitative research, though hardly comprehensively. They focus on mainstream accounts.

Most standards for studies and manuscripts offer a set of general guidelines for authors. In education, [American Educational Research Association \(2006\)](#) offered standards for all empirical publications, including qualitative studies. The 42 main standards are realist in orientation; epistemology is not mentioned in the document. The AERA standards do include attention to research ethics and a strong focus on establishing the evidence that supports each conclusion. Similarly, in medicine, [O'Brien et al. \(2014\)](#) created a set of 21 broad standards for reporting qualitative research, synthesizing the recommendations of others across professions. In 2018 the American Psychological Association published its recommended "JARS" or "journal article reporting standards" for qualitative research ([Levitt et al., 2018](#)). The detailed, four page, list seeks to address a range of study types and writing styles. It does not offer much guidance for studies not premised on science, though it mentions narrative reporting styles. Epistemology is not mentioned as an important orienting choice for researchers, nor is self-reflection mentioned, though author reflexivity is included in terms of a structured way to enhance methodological integrity. Another checklist is [Tong et al. \(2007\)](#) Consolidated Criteria for Reporting Qualitative Research (COREQ). This checklist draws attention to three areas (research team and reflexivity, study design and data analysis, and reporting) and covers many details in its 33 items. Some journals may require submission of the COREQ or other checklists as part of the submission process. However, JARS and COREQ may not fit well with more contemporary qualitative inquiry efforts. Such checklists are useful guides for some qualitative research projects but others may find them limiting or confining.

All checklists for qualitative studies and reports focus attention to topics that are likely concerns of reviewers, and in this way can be useful to authors. On the other hand, checklists may fail to address all forms of contemporary qualitative research and inquiry ([Kross and Giust, 2019](#)). For example, [Cheek \(2008\)](#) notes that standardization of qualitative research may force authors to conform to views that may not match their purposes, research approaches, or collected data. Checklists may be a valuable tool for beginners, but may artificially and unnecessarily limit innovation in qualitative research. Standard checklists also fail to address the growing interest in qualitative inquiry, in which scientific standards may not be the researcher's orientation.

Finding the right journal or publisher

It is pivotal to effective qualitative research writing to determine just who is your intended audience. By this I mean to whom do you seek to inform, persuade, or give testimony? A key component of traditional academic publishing is determining the best few journals to which to submit. This is often based on the journal's impact factor. Journals serve as gatekeepers to these readers as well as providing a service of organizing and presenting the research. They also match readers and research writers.

To identify a target journal for a study, it is often helpful to reflect on the journals that were most useful in framing the current research literature and methods. These are often good targets for your publication as they publish similar topics using similar research approaches and methods. Journal mission statements may also clarify the kinds of topics and methods being sought for publication. Journal web sites provide details about the length, format, and other requirements for submissions. Reviewing these statements can further clarify if a journal fits a specific research manuscript.

There are many online resources to aid in selecting a target journal for one's work. Simple searches can reveal lists of professional journals along with their impact factors and other useful information. For example, [ERIC \(2020\)](#) offers a huge array of education publications ranging from journals to conference proceedings. The ERIC list may be searched selectively or comprehensively, and can be set to search only for peer reviewed publications, or only for those available free in full text format. While comprehensive, it is easy to be overwhelmed by so many choices. [Scimago Lab \(2020\)](#) lists international journals in education by several journal and individual impact factors. Sometimes the best target journal will be outside one's home country. Online tools such as [Elsevier's \(2020\) Journal Finder](#) may also narrow a list of likely target journals. All such lists and tools may guide us, but the final choice of target journal requires additional critical thinking.

For longer works, a monograph length publication may better capture the detail and complexity of the research. Monographs are typically reports that are well over 20 double-spaced pages, and may be much longer. Some publishers will publish monographs on specific topics; this is an option that qualitative researchers should explore for extended works. A monograph, according to Case (2009) is "a large, specialized work of scholarship that treats a narrow topic in great detail," and that focuses on "establishing facts or narrative in a set of fields in which facts and narratives are often hard to establish" (p. 4). Monographs target very specific and specialized audiences. Alternatively, some longer works may be divided into two-part article publications. These are often published in the same issue or may be published in two successive issues. For example, [Shields and King \(2001a,b\)](#) reported a large qualitative study addressing hospital services in four countries in two articles published in successive journal issues. Similarly, [Petty et al. \(2012a,b\)](#) used a two-part article to first explore the philosophical underpinnings of qualitative research. They next linked this discussion to an empirical analysis of specific named qualitative research approaches in the second article.

Submitting and being reviewed

Once a manuscript is submitted for publication, it is typically reviewed by two or three anonymous referees or jurors. These reviewers are typically successful academics with depth knowledge in the specialty areas of the target journal. Sometimes reviewers are selected from researchers who have written extensively on a topic or who have particular expertise in the topic area ([Allen, 2016](#)). The identities of authors and reviewers are kept anonymous from each other during the review process to limit bias. Reviewers are

rarely publicly identified in ways that link them to specific reviews. They are, however, sometimes acknowledged by the authors and named after acceptance when they have made particularly valuable comments or additions to the manuscript. Bear in mind that reviewers are asked to serve as critical readers who appraise both the strengths and the limitations of manuscripts. Of course, reviewers ideally review manuscripts using approaches and methods which they have some familiarity. Key issues include clarity of the research question or topic, a reasonable literature review, and internal consistency among epistemology, research approach and methods employed. Staying close to the data or evidence is always wise.

Reviewers are not solely serving as educators for authors; they must instead ensure that published works are sound, clear, and rigorous. Reviewers are usually asked to return completed reviews within three weeks or less of assignment. This is done to keep overall publication turnaround time to a minimum. Reviewing is an academic “service”, meaning it is an unpaid role necessary for the professions continuation but is given little reward toward tenure and promotion (Staller, 2013). It is a process vital to academic publishing.

Once all reviews are submitted, the editor-in-chief makes a publication decision on the manuscript. Decision options generally include (1) accept as is, (2) minor revisions needed, (3) major revisions needed, (4) reject, or (5) the manuscript should be directed to another journal which better fits its content and focus. Full accepts are rare, while revision requests are common. The journal editor will send a decision letter or email to the authors. The letter states the decision and if revisions are recommended, includes statements and suggestions from the reviewers. Some journals set a deadline for revisions to be completed and the manuscript resubmitted. Quick revision is best.

In responding to recommendations for revisions, the authors should list every critical comment from each reviewer and then show specifically how the concern has been addressed. A literal numbered list of comments by each reviewer and author replies is useful. Such a list documents the authors’ responses and that all revisions were made. Be sure to address all stated concerns. However, if the reviewer’s concern seems inaccurate, or would lead to other problems, it is fine to explain why the content was left as is. Of course, editors and reviewers may not agree with the author’s logic.

Once the authors submit the revised manuscript, the journal editor sends the referees the revised manuscript. Another timed cycle of reviews by the same referees begins. At the end of the second review, the authors are presented again with a decision on the revised manuscript.

From acceptance to publication is a process with no fixed time frame. Publications lag may be short or quite long. Some journals have significant print backlogs, and in turn offer “online first” publication in which the article is made available online electrically before it is assigned to a specific print volume, issue, and final pagination.

Reviewing

Reviewing qualitative research and inquiry manuscripts is another important role in the professions for which education and preparation is limited. The literature on conducting manuscript reviews is also quite small. It seems that grading student papers is taken as an adequate introduction to reviewing professional publications; though the content and methods of academic manuscripts are often novel and innovative, perhaps even unfamiliar to their reviewers. The challenge of a manuscript review is quite unlike grading an academic assignment one has personally created on familiar content. A benefit of doing journal and book proposal reviews is that one is exposed to the latest issues, and sometimes to cutting-edge ideas and methods. At times reviewers recuse themselves from reviews when they can determine the identity of the author; or when the reviewer may be a colleague or competitor. To limit bias, reviews are intentionally “blind” with neither the authors’ nor the reviewers’ names revealed during the process.

In doing a review, I find that a quick read through of the full manuscript is best followed later by a slower and closer look in which I make specific comments linked to text (Drisko, 1999). Staller (2013) cites Lee’s (1995) list of items to consider when reviewing a manuscript. Lee begins by summarizing the manuscript as read. I also summarize “what I’ve read” at the start of my own reviews. This process helps identify omissions of content (i.e., no named method, no mention of an IRB review) and makes clear to the authors that one has read the manuscript. Following this overall summary, reviewers should provide detailed comments that are each specifically linked to content by page and line numbers (The pdf versions of manuscripts created during the electronic submission process typically adds page and line numbering). Strengths and concerns should be specifically identified. Actionable comments are very useful (Lee, 1995). Reviewers seek clarity of topic or question, details on the selected qualitative research approach, and details on the sample employed and a short rationale on its selection and merits. Reviewers look for a “road map” that guides them through the material in a useful manner. A statement of how human research participants were protected during the study and the write up is always expected—and is oddly often neglected. Reviewers also look at the quality and clarity of the writing, its direct linkage to the collected data, and some reflection of the strengths and limitations of the methods employed are expected. Conclusions and recommendations must stay close to the reported data.

Lee (1995) also calls for reviewers to be kind and thoughtful of the authors. It is good to be frank but not to be devaluing. The worst reviews are short, negative comments that do not guide the authors to improve their work or to learn needed content. Reviewers should also state how their expertise is limited if it impacts their ability to complete the review and point to needed revisions. I had a manuscript turned down by a reviewer who explicitly questioned what “triangulation” was in the content of a study that purposefully compared and contrasted (triangulated) the views of adoptive parents, child welfare workers, and therapists. The reviewer demonstrated that they were not qualified to do a review of this manuscript, but they did not recuse and instead rejected (slammed?) the study apparently based on limited knowledge. Reviewers hopefully maintain a helpful and supportive approach

even while pointing out the limitations of a manuscript. Providing specific guidance on areas of concern found in a manuscript is a valuable professional service—to the authors and to future readers.

Authors frequently find reviewers' comments to be conflicting or inconsistent (Staller, 2013). Such differences may be due to differences in expertise or experience among reviewers; differences that are purposefully sought by journal editors. The goal is to point out potential concerns in a manuscript to guide its improvement. Author, reviewers, and readers may bring different perspectives and even different epistemologies to their reads of a manuscript. Through the review process a dialog is begun among these people, ideally improving the final version of the article. Staller (2013) notes that inconsistent reviews may suggest that the authors must make their thesis clearer, or to more fully and transparently invite and guide readers through the material and conclusions.

As a reviewer, I find it quick and easy to read through well organized and clearly written manuscripts. This is in large part because the author is effectively guiding the reader through the material. Good headings and transitions between paragraphs and sections also help build flow. In contrast, I can spend hours reading through materials that do not seem clear as I attempt to develop a narrative line of my own to integrate the material—a story line which will become a key part of my review content. Authors need to provide a transparent road map through the literature, the relevant empirical studies, and the relevant research approach and methods. Where these are lacking, inconsistent reviews may reflect different “reads” of the material by reviewers.

Poor spelling, changing verb tenses, omitted words, and even shifts in the overall “voice” of a manuscript also suggest more care is needed before submission. One of the most difficult aspects of professional writing is proof reading. Reading each sentence aloud, slowly and carefully, can help identify problems in structure and grammar. It is a challenging process that takes time and cannot be done successfully if rushed. Another option is to ask a skilled colleague to carefully review the manuscript. This often sets up a later return of the favor for the colleague at another time. Graduate students often comment that this process is very different from grading where specific content is sought. Organization, clarity, and flow of ideas is instead the main focus of late-stage manuscript preening.

Conclusions

Writing up qualitative research takes attention and effort because there are so many qualitative research approaches and so many methods of qualitative inquiry. These may be scientific or not, may draw on many different ways of knowing such as Indigenous methods or participatory action research in which power differentials between researchers and participants are altered, and autoethnographies that offer the views of the author in social context with attention to aesthetics. Yet we learn by writing and the thinking it requires. We may find new dimensions of content, refine our knowledge of concepts and theories, and get clearer on our ideas as we write. Thinking, writing, and learning all merge and intersect in professional writing.

Offering our ideas publicly benefits our readers who learn from us, and can benefit authors in supporting their academic careers. Writers also learn about topics of interest. Outside the academy, offering our ideas to others provides a forum for feedback that can help us expand, correct, deepen, and clarify what we know. Writing up qualitative research informs others. What others can learn from our research work includes content, epistemologies and ontologies, values, approaches and methods, and how we organize and write up our qualitative research work. With feedback from others and self-reflection, we learn how effectively our written work has educated others, what our strengths are as researchers and writers, and which areas need continued attention to improve our effectiveness as researcher and communicators. Developing excellence in qualitative research writing is best understood as a career long endeavor.

Mixed methods research (MMR) involves collecting and analyzing both quantitative and qualitative data within the same research study. More specifically, MMR is considered “research in which the investigator collects and analyzes data, integrates the findings, and draws inferences using both qualitative and quantitative approaches or methods in a single study or program of inquiry” (Tashakkori and Creswell, 2007, p. 4). Although MMR was conceived as a distinct research method in the 1970s/1980s, it was not until the early 2000s did it begin to grow in popularity (Creswell and Plano Clark, 2018). Now MMR can be seen as a third distinct research method to accompany quantitative and qualitative approaches. MMR is now a common research approach used in a variety of academic disciplines including the health sciences, education, and the social sciences.

Regardless of the academic discipline, in order to engage in a good MMR study, it is necessary to have a research plan, to begin with a research proposal. The purpose of this chapter is to discuss the importance of the mixed methods research proposal (MMRP), how it is used, and its various components. We will begin our discussion by describing the goals of the MMRP. We then provide details regarding the different sections or components of the MMRP. Last, we discuss challenges or issues associated with writing a MMRP. We also provide resources on how to write research proposals and how to conduct mixed methods research for a research study and/or a funding agency.

What is special about a mixed methods research proposal?

Researchers cannot undertake a study without having a plan. Therefore, every research study requires a detailed plan of action. In the case of MMR, the plan is called a mixed methods research proposal (MMRP). The MMRP is a detailed research plan that describes the steps that are required and needed to undertake a MMR study. The MMRP outlines everything that will be done within the study,

Table 1 Components of the mixed methods proposal.

as well as provides parameters for what will not be done within the study. The MMRP is tentative in that it is subject to change and should be seen more as a flexible contract between the researcher and their stakeholders. However, researchers should follow the proposal as closely as possible and deviate only when extremely necessary.

According to [DeCuir-Gunby and Schutz \(2017\)](#), the MMRP has three major sections (introduction, literature review, and methods) and two minor sections (references and appendices). See [Table 1](#) for a listing of the proposal components. The three major sections are the most important sections of the proposal. The introduction section provides an overview of the entire proposal by focusing on the research aims and purpose. It also provides the conceptual framework or inquiry worldview that guides the study. The literature review helps to situate the study into a larger context by making connections to the extant literature. The methods section focuses on the actual data collection and analysis process, including a discussion of data integration, a major component of mixed methods research. The two minor sections, the reference section and the appendices, are both needed as support for the three major sections. The reference section lists all of the citations used to create the document. The appendices are a collection of documents that are relevant to understanding the proposed study and help to provide the needed context for the study.

There is no standard way or a set of common rules to develop a MMRP. According to [Hesse-Biber \(2010\)](#), a MMR study can be qualitative-dominant (emphasis on the qualitative aspects), quantitative-dominant (emphasis on the quantitative aspects), or mixed (emphasizing both the qualitative and quantitative components equally), which in turn will influence the manner in which a MMRP is developed. There is also variation depending upon academic discipline as well as research proposal type including dissertations/theses, grants, and general research studies. However, there are components that should be included in all MMRPs. The remaining discussion will focus on the components that should be included in all MMRPs, with distinctions being made for research proposal type when necessary.

Components of a mixed methods research proposal

As previously mentioned, there are three major components (introduction, literature review, and methods) and two minor components (references and appendices) of a MMRP. However, within these components, there are several sub-components that are central to developing a MMRP. The explanation of the introduction includes a discussion of the research background, research aims, and the conceptual framework/inquiry worldview. The literature review discusses how the research literature is explored and connected to the research purpose. The methods section involves an explanation of research questions/hypotheses, mixed methods designs, sampling/participants/context, data collection procedures, data analysis procedures, data integration, and data validation. For this discussion, the references and appendices are explained in a combined section. The importance of the references are explored as well as what is to be included in the appendices such as the mixed methods procedural diagram, IRB protocol, questionnaires/interview protocols, timelines, and budgets.

Introduction

The introduction provides necessary background information and gives readers an overall sense of the research topic. This section of the proposal is important because it allows readers to explore the problem that needs to be solved by the research, the current state of the topic, issues or controversies surrounding the topic, the goals of the research, potential policy implications of the work, and how the researcher's perspective will inform/guide the study. While this section is typically one of the shorter sections of the proposal, a concise, succinct approach is needed to effectively convey the researcher's stance on the topic. Thus, to begin this section, the writer should situate the study, provide empirical evidence and references regarding where the study stems from, provide an overview of what will be shared throughout the proposal, and most importantly engage the reader in a way that if they are unfamiliar with the topic, they can easily understand the content that is being discussed.

Background

Framing a background or problem statement allows knowledge gaps and issues to provide context for why the study is necessary. This should be stated clearly, and should be a focused statement on the constructs that will be addressed within the research study. This section can highlight statistics on the topic of interest, briefings on the topic, history of where the field stands on the subject matter, and a clear delineation on where future research or the current proposal aims to add to the current literature in the field.

Research aims

It is essential that the proposal have a clear description of the goals or what the researcher hopes to discover within the proposed study. While the goals of the study may change, knowing how to focus the study will help the researcher address the key concepts. Along with including a rationale for the study, the researcher should specify why this work is different from other work that has been previously conducted, discuss the significance of how the approach will generate new knowledge, and explain general understandings regarding the topic. MMRP aims align with the components of the design of the study. For example, in a sequential design, the researcher could focus on the quantitative aim before moving to the qualitative aim. Also, the aims can be qualitative, quantitative, or mixed methods focused. Some common mistakes made within MMRPs include having too many aims, being vague, or developing unachievable goals. When developing research aims, make sure they are measurable and can be realistically achieved with the given time frame. These aims will guide the study as they provide further context regarding what the researcher intends to achieve by carrying out the study in its entirety.

Conceptual framework/inquiry worldview

The conceptual or theoretical framework is a broad set of ideals used to guide and understand the development of the research process. Oftentimes in research, one theory cannot sufficiently address all of the issues or frame the problem that needs to be solved. A theoretical framework is based on existing theories and models that ground the study. A conceptual framework is a display that demonstrates how constructs are connected based on what the researcher intends to observe in the study. Thus, instead of just using a theoretical framework, a conceptual framework allows for multiple theories to situate the research study. [Creswell and Plano Clark \(2018\)](#) suggest using the theory to guide all aspects of the research such as questions, variables, analysis, and integration. By using concepts, relevant literature, and models relevant to the problem, the framework helps guide the researcher to evaluate the MMR in a more critical manner (see [Shannon-Baker, 2022](#)).

In addition to the theoretical perspectives that will guide the research, the researcher's individual experiences and beliefs, also known as the inquiry worldview ([DeCuir-Gunby and Schutz, 2017](#)), will guide the direction of the proposal. Being able to identify how the researcher's multiple identities (e.g., race, gender, religion, socioeconomic status, geographic location) contribute to the process in which they engage with data collection and data analysis, as well as how the writing is influenced is essential. The interpretation of research allows readers to make meaning based on the results that are reported, which is related to the subjectivity and voice of the researcher. While some may interpret their own inquiry worldview as problematic, this is the true nature of how research evolves, so it is vital that the researcher remains aware and conscious of personal biases and share them with the reader within the proposed research.

Literature review

The literature review provides a foundation for the entire proposal. Within this section, it is important to highlight the gaps within the existing literature as well as define the constructs, theories, and other information that is needed for the reader to understand the proposed study. While the researcher may not have read everything regarding the content area, this section should demonstrate that the researcher is an expert when it comes to the problem that is being addressed. To complete the literature review, the researcher should engage in a critical analysis of how the literature has evolved over time. By reviewing seminal pieces related to the topic as

well as recent developments within the past 5–10 years, the work should discuss what scholars have written about the topic that is being studied, the theories utilized, and how this connects to the approach that the researcher will use. As indicated by [Xiao and Watson \(2019\)](#), the inclusion criteria used within search engines can assist in the searching of articles that are relevant to the research pertinent to the study. The literature review should provide a clear explanation of why specific theoretical frameworks, constructs, and/or methodologies should be utilized to address the particular issue and questions that guide the study.

Within the literature review, the researcher should demonstrate the individuality of the research problem that is being presented. After sharing the big picture of the gaps in the literature, the review should situate the current topic among the larger discipline work. It should also discuss why using mixed methods research may provide stronger evidence for your research. While developing the literature review, using a reference manager or spreadsheet may assist with the organization of ideas such as the specific citations, research questions that are addressed, the approach/theoretical framework, measures utilized, analysis, key findings, and other notes that can guide the study. This synthesis can provide guidance for how the researcher should approach the study methodologically. Moreover, the literature review should not be a list of all the work that has been done, rather it should provide a more conversational tone of the vast or dearth of literature that is present, allow the researcher to justify why the work is needed, and state how the research can benefit society in the future.

Methods

The next section, the methods section, is perhaps the most important component of the MMRP. As described by [DeCuir-Gunby and Schutz \(2017\)](#), it is the “heart of the mixed methods research plan” (p. 107). The methods section explains the specific data that will be collected, how the data will be collected and analyzed, as well as the validation and reliability process. Because this is a mixed methods proposal, the methods section also discusses aspects that are specific to mixed methods research including the mixed methods design to be used and data integration plans. The methods section is comprehensive and extremely detailed. It is necessary that the researcher painstakingly describes all steps of the research process for readers within this section of the proposal. It is important that the subcomponents of the methods sections adhere to the particular mixed methods design chosen. For instance, if using one of the sequential designs, it may be necessary to discuss the different subcomponents according to the design phases. Ultimately, the subcomponents of the methods section are all necessary for a MMRP although the order may differ based upon academic discipline or personal writing preferences.

Research questions/hypotheses

The first section of the methods section is generally the discussion of the research questions/hypotheses. Research questions are the questions that are guiding the research investigation. Hypotheses are the specific relationships that are to be tested within a study. It should be noted that qualitative studies do not focus on hypotheses while quantitative studies generally feature research questions or hypotheses. In a mixed methods study, research questions can be quantitative ([Onwuegbuzie and Leech, 2006](#)), qualitative ([Agee, 2009](#)), or mixed methods ([Clark and Badiee, 2010](#)). Research questions are important because they help shape the components of the proposal. Although we recommend including the research questions within the research methods section, many researchers often include the research questions within the introduction section, particularly in dissertation proposals.

Mixed methods designs

Different research questions are best answered by using specific mixed methods research designs. In mixed methods research, there are five basic or core designs: explanatory sequential (e.g., qualitative data explaining quantitative data), exploratory sequential (e.g., quantitative data building upon the qualitative findings), convergent parallel (e.g., quantitative and qualitative data collected and analyzed separately but findings merged), embedded (e.g., qualitative data embedded within quantitative data), and multiphase (e.g., the alternating of quantitative and qualitative phases) ([Creswell and Plano Clark, 2018](#)). There are also more complex, advanced mixed methods designs that can be used such as case study mixed methods designs ([Cook and Kamalodeen, 2020](#); [Guetterman and Fetters, 2018](#)), action research mixed methods designs ([Ivankova and Wingo, 2018](#)), transformative mixed methods designs ([Mertens, 2012](#)), scale development designs ([Taghipoorreynah and deRun, 2020](#)), mixed methods phenomenological research ([Mayoh and Onwuegbuzie, 2015](#)), and fully integrated mixed methods designs ([Creamer, 2017](#)), among many others. For more details regarding mixed methods designs, see [Creswell and Plano Clark \(2018\)](#). Regardless of the chosen design, it is imperative that the designs are explained in detail. The mixed methods design will dictate how the data are collected and analyzed, as well as provide a framework for how the final write up will be organized or even disseminated. There can also be variability across disciplines in how designs are implemented.

Mixed methods procedural diagram

The MMRP should include a visual of the mixed methods design. The complexity of mixed methods research can make it difficult to articulate and describe what is needed to execute the research. A visual or graphic, also known as a procedural diagram, can be utilized to easily communicate the sequence of the design, as well as the procedures, and products that will be produced

throughout. [Ivankova et al. \(2006\)](#) suggest ten rules to drawing a procedural diagram for mixed methods research. The procedural diagram should have a name/title that is reflective of the research design that will be used, can be positioned in a vertical or horizontal manner, and boxes should include all stages of the research for quantitative and qualitative data collection, analysis, and integration. Arrows and proper nomenclature will allow the reader to understand the focus of the design, the approach, and what type of research is more dominant. Providing a descriptive procedure for data collection and analysis, as well as what will result from the data collection (e.g., artifacts, transcripts, survey data), will help connect the sequence of events with the expected products that will guide the results. The model will serve as a guideline as to how the research will be completed, making it easier to share the direction of the research with others.

Participants/context/sampling

In addition to explaining the design, it is important to discuss who will be involved with the data collection process. More specifically, the methods section involves a detailed discussion of the participant descriptions, the context involved in the study, and the sampling methods. It is imperative that the researcher understands the study's population of interest. Providing a description of the qualities and demographic characteristics that the participants will possess is necessary to help the readers better understand how the research questions will be addressed. Once the participants are determined, it will be essential to choose the appropriate context(s). The context is the environment in which the participants live, work, and/or experience the phenomena of interest. Sometimes the context is just as important as the actual individual participants. Providing a description of the research context provides more background information regarding the participants in the study. As such, sampling in a research study is extremely important. The sampling method is the strategy used to gain access to the data in the study, particularly any participants that will be actively involved. According to [Collins et al. \(2007\)](#), in mixed methods there are four major types of sampling: identical sampling (the same participants are used in the quantitative and qualitative phases), parallel sampling (different participants from the same population are used in the quantitative and qualitative phases), nested sampling (a subset of participants in one phase participates in the other phase of the study), and multilevel sampling (different people from the population are used for the various phases of the study). Describing the sampling process is necessary for helping to determine the manner in which the data are collected.

Data sources

Within a methods section, it is necessary to list and describe in detail the data that will be collected or used in the study. Some studies rely upon existing data sets (e.g., previously collected national longitudinal data set) or artifacts (e.g., historical documents) while others may require the researcher collecting new data sources. Common quantitative data sources include survey instruments, tests (e.g., psychological, physiological, academic), and observation protocols. Qualitative instruments often include interview protocols (individual or focus group) or observation protocols. Regardless of the type of data source, the researcher should fully describe the instrument including the purpose, the structure, and any reliability/validity information that is available. Also, when describing the data sources, it is important to distinguish between both the quantitative and qualitative data as well as any data sources that could be analyzed in a manner that results in both quantitative and qualitative data.

Data collection procedures

It is necessary to explain everything about the data collection process. As stated by [DeCuir-Gunby and Schutz \(2017\)](#), this includes the *when*, *where*, *how* and *why*. The researcher must explain *when* in terms of the time of day, month, year, etc. *Where* involves explaining the context (e.g., participants' homes, on campus, at a hospital) of the data collection. The *how* gets into the explicit details. It involves providing all of the steps that are needed to collect the data. How will the researcher get access to the existing data or the participants? What will be the role of the participants? What will the participants do? How long will the tasks take? Then the researcher will need to address the *why* in terms of explaining how all of this will be done and why these steps are necessary.

Data analysis strategies

After the data are collected it will be analyzed. Thus, it is imperative that the researcher have a thoughtful plan for data analysis. The data analysis plan should involve three major stages: data cleaning/organization, data exploration, and final data analysis. There should be a detailed plan for how the data will be cleaned and organized once it is collected. This will include how any software will be used for data management. Data cleaning/organization involves searching and replacing missing data as well as creating code books for both quantitative and qualitative analysis. Data cleaning/organization may be one of the most undervalued yet most essential steps in a research study. The manner in which data are cleaned and organized has the potential to impact the quality of data analysis. As such it is recommended that the researcher invest substantial time in this stage. After the data has been thoroughly cleaned and organized, it is important for the researcher to explore the data noting trends. In terms of quantitative data this will involve descriptive statistics. For qualitative data this may involve reading interviews and writing memos regarding potential themes. Exploratory data analysis is helpful in terms of determining the next best steps for analysis. It's possible that based upon the trends found in the data that new data analysis strategies may emerge, or changes may have to be made regarding the planned data analysis strategies. The last stage is the final analysis stage. This is where the researcher describes in detail how the data will be

analyzed. In terms of the quantitative data, specific statistical procedures will be described. For the qualitative data, the coding process will be described including how codes will be created and applied to the data. It also involves describing how the inquiry worldview will be used within the data analysis process. Researchers can also engage in mixed methods data analysis which involves the mixing of quantitative and qualitative data concurrently or sequentially (Onwuegbuzie and Teddlie, 2003).

Data integration

A core component of mixed methods research is the integration of the quantitative and qualitative data. The MMRP must describe how the quantitative and qualitative data or findings will be mixed or integrated. Data integration is important because it illustrates what was found in the study and why the collection of both quantitative and qualitative data were important for your study. Data integration can occur in the form of merging (combining the quantitative and qualitative data or findings), explaining (using one form of data to explain another), building (using one form of data to build upon another), or embedding (one form of data are embedded within another form of data) (Creswell, 2014). Data integration can occur in any stage of the research process, but most researchers engage in data integration during the data interpretation and reporting stages. According to Fetters et al. (2013), the common data integration approaches are narrative (integrating the quantitative and qualitative findings in a narrative account), data transformation (quantifying qualitative data or qualitzing quantitative data), and joint display (using visualizations to represent the data) (see Guetterman, 2022).

Data validation and reliability

The last subcomponent of the methods section discusses the data validation process, or legitimation (Onwuegbuzie et al., 2011). Data validation involves discussing the process for determining whether or not the claims being made are accurate while reliability addresses whether or not claims are consistent. In qualitative research this is often described as trustworthiness and credibility (Lincoln and Guba, 1986). Within mixed methods research, there needs to be a plan for how validity/trustworthiness and reliability/credibility will be addressed in terms of the separate quantitative and qualitative components as well as the mixed methods study as a whole. Mixed methods validation is concerned with inference making, specifically the metainferences that are being made from the combining of the quantitative and qualitative data (Tashakkori et al., 2021). It is also important to consider the consequences of the study and how the findings will be used (Dellinger and Leech, 2007).

References and appendices

The last section of the research proposal includes the references and the appendices. The references and appendices include working sources that guide or inform the research that will be conducted. Citations that are included in the proposal should be presented in alphabetical order according to the publication manual that guides the researcher's academic discipline (e.g., MLA, APA, Chicago). Additionally, some citations should be referred to in numeric order, based on the discipline (e.g., Vancouver, AMA, IEEE). The appendix section, on the other hand, allows the researcher to share any relevant information that could not be added within the proposal narrative. The information included in the appendix section depends upon the purpose of the proposal and what stakeholders may need to review the proposal. The appendices should include information such as the mixed methods procedural diagram, the Institutional Review Board (IRB) research protocol, and other documentation that is used for the prospective research.

Institutional Review Board documents

Some, not all, researchers like to include copies of their IRB application. An IRB reviews the methods that will be used to execute research to ensure that it is ethical. To protect participants, the IRB board monitors the safety of the research design by examining the materials (i.e., interview protocol, experimental design, recruitment flyers, data management), as well as reviewing updates and changes throughout the research, such as participants that withdraw from the study, protocol deviations, and amendments. IRB and ethics boards in numerous countries may have varying foci and regulations. DeCuir-Gunby and Schutz (2017) mentions meeting with IRB staff and discussing the IRB process with others as a way to learn about the process before encountering it. When the IRB is submitted, all protocols and surveys must be included, as well as information regarding how data will be shared with other researchers and how anonymity will be maintained among participants. Potential risks and a plan of action will also need to be detailed should one of these risks present itself to a participant. This information is often included in a MMRP, particularly in dissertations. An IRB board consisting of a committee with various backgrounds will convene and decide whether the study should be approved based on the risks and benefits of the study. It is important to note that should any changes come after initial IRB approval, these should be communicated immediately to the IRB board. Questionnaires, interview questions, and the associated protocols may need to be amended throughout the phases of the study because of changes to the research staff, funding sources, study sample, data findings, data storage, risks associated with the study, or changes in confidentiality. MMRP that are sequential may build on the protocols throughout the duration of the study based on data collection and analysis of the quantitative or qualitative data.

Questionnaires/interview questions

The MMRP should include copies of all questionnaires, tests, and interview protocols to be used in the study. To serve as a reminder to the researcher/interviewer before preparing to disseminate questionnaires or conducting interviews, a protocol is a guide to determining the key components and information that should be collected from the research participants. The interview protocol, specifically, may begin with a script of what to say before the interview begins or pertinent information that is needed before completing a questionnaire. This should address issues of confidentiality (in some instances participants can disclose a pseudonym to be used throughout the interview) and also remind the participant of the informed consent that they have/may need to sign. To make the participants more comfortable, the researcher(s) should also introduce themselves by including information such as their name, background/position, and why they are conducting the study. Clear, concise language should be used to alleviate any concerns from the participant. In addition, at the end of the questionnaire/interview, a closing script should provide information regarding how to contact the researcher/interviewer should the participant need to clarify anything throughout the duration of the study.

Timeline

Although not required, many MMRPs often include timelines. Timelines are particularly helpful for grants and dissertation proposals. Developing a schedule or timeline will provide a realistic plan based on institutional or organizational deadlines. By goal-setting, the researcher can understand all the elements and tasks that must be completed throughout the duration of the research. While planning, the researcher should account for elements such as IRB submission and approval, study design execution, and purchasing supplies. However, many of these tasks will take longer than anticipated. One should ask, how long will it take to organize survey data, clean and transcribe transcripts, run analyses and code data, as well as integrate the findings before actually writing up the findings of the study? Therefore, making a plan allows the researcher to effectively engage in time management and to execute the research proposal in an efficient manner.

Budget

Whether you are applying for funding or your research is self-funded, a budget can assist the researcher in planning the research in detail and allow the researcher to assess the use of funds throughout the duration of the study. Including a budget is a requirement for grant proposals but generally helpful for dissertations as well. To develop a budget, first list all the activities needed to complete the research (e.g., research equipment, study materials, transcription services, data analysis software costs, participant compensation). Consulting with the university or institutional regulations regarding budget spending will allow the researcher to examine that they are using the funds as outlined by the guidelines. While it may seem like paying participants or using two transcription services is allowable, every organization has specific rules about fund usage. After doing this and estimating (as closely as possible) what the intended costs are, utilizing a spreadsheet to make cost estimates, considering the scope of the research, will provide a method to calculate costs. Lastly, for each item be sure to justify why the expense is essential to the research.

Issues to consider when developing a mixed methods research proposal

When developing a MMRP, the nature of the research can allow for various issues to arise when planning, developing, and executing the research. The amount of skill level needed to produce the proposal requires researchers to consider multiple facets of the process. The execution and writing delivery of the proposal, data management, and extenuating circumstances can all contribute to the success or demise of the proposal. In order to address these potential issues, it is important to consider supporting and guiding resources (see [Table 2](#)).

Title

It is important to create a title that captures the essence of the proposal. Specifically, [Creswell and Plano Clark \(2018\)](#) suggest that titles for mixed methods proposals should include the participants and location of the study, the phrase “mixed methods,” as well as reflect the type of mixed methods design being used. What is most important is that the researcher captures the main topics/constructs and populations of interests. When creating a title it is important for the researcher to keep in consideration the academic discipline’s publication manual requirements for the title’s word limits.

Abstract

This component of the proposal provides the essence of the paper in brevity, before going into further detail. It allows readers to decide whether or not the research is of interest to them. By using approximately 100–350 words, the informative abstract should introduce the research problem and indicate why the research problem is important. This can be done by providing an

introductory sentence with historical background, identifying the purpose, theoretical framework, study methodology, procedures, and key findings or predicted findings. To conclude the abstract, share recommendations and implications that capture the nature of how the work can impact society. The researcher should be concise, clear, and not include references in this section. In some instances, abstracts may ask for less than 100 words (i.e., descriptive abstract), which will require the researcher to provide less detail and highlight only key components of the work. Writing this section toward the end of the proposal development may be easier considering that the researcher has gained clarity on what is needed to execute the study in its entirety (DeCuir-Gunby and Schutz, 2017).

Data management

Throughout the research process, there will be a host of materials that will need to be organized, stored, and shared with others. The daily management of these resources require consistent conventions that will allow the researcher to easily access and archive the materials since MMRP usually contain a large amount of qualitative and quantitative data. Therefore, it is necessary to understand how to be strategic regarding the organization of data, how to integrate data to fully answer the aims of your study, and how to leverage the resources needed to access and store data (see Niglas et al., 2022, Chapter 11063). Data can include anything such

as audio recordings, surveys, physical artifacts, images, etc., and effectively organizing these materials will save the researcher time, stress, and in the long run, reduce the amount of errors that can lead to poor data analysis and validity, as well as risk the anonymity of the participants' information. When considering how data will be managed, exploring the university or organizational processes and policies is vital. Each entity may have different rules and regulations regarding what type of data management system must be used. For example, the researcher may want to use Google Drive, but the university utilizes a password protected drop box program to protect their data. Depending on the amount of data, the kind of data, privacy, and the roles of other researchers on the research team, the data management system that is utilized should consider all of these factors.

Extenuating circumstances

Unprecedented occasions may push researchers to seek guidance outside of the typical IRB guidelines to conduct research in an ethical manner. During the COVID-19 pandemic, while research is a major function of many universities and other institutions, it is critical that researchers follow the strict guidelines provided by state mandates to maintain personal safety and the safety of human subjects. Thus, in order to continue to transform the research community, researchers should look to collaborate based on financial and personal constraints and provide good leadership during difficult times to build a better research culture. While research is important, it should not risk the well-being of those that are being studied. Researchers should consider ways in which the study can be conducted without harming those that are being studied and evaluate the effectiveness of their research design within the parameters of extenuating circumstances.

Technology usage

When conducting research, many researchers engage in technology usage. Whether it be a software program for data analysis, voice recorders, a PowerPoint presentation, or a tool that is used to conduct the research, all of these are utilized for the completion of the study (see Kuckartz de, 2022). Technological advances allow researchers to conduct the study in an effective, timely manner, but the researcher should always consider what process will occur when technology fails or is inaccessible. Technology has varying costs so budgeting the cost of software programs based on the amount of time they will be utilized, as well as investigating what resources can be accessed at a reduced or no cost should be considered. In addition to costs, creating a system to effectively collect and retain technology (e.g., voice recorders, iPads) that participants may use is vital, so labeling them in a way that is easily understood and providing protective covers may be necessary. The other consideration is what to do when technology fails. This is something that no one wants to deal with, but we know that it can happen and often cannot be prevented. Thus, checking the technology before it is used is important and having a backup is always good. Taking preventative measures such as keeping paper copies of surveys, interviews, and backing up data throughout the research process can assist with technological issues throughout the proposal and executions phases.

Conclusion

Writing a MMRP can seem like a daunting task. It requires the understanding of mixed methods research approaches, the proposal writing process, as well as how to merge the two approaches. Like with any research proposal, a MMRP requires a lot of time and planning. Depending upon the purpose of the proposal, it may even require a team approach. Following the recommended guidelines for writing a MMRP is necessary for a successful proposal development process. Regardless, executing a well-planned and detailed MMRP will enable a comprehensive and successful research study.

Reporting mixed methods research studies

Conducting mixed methods research (MMR) can capitalize on the strengths of both quantitative methods and qualitative methods to yield “stronger and more credible evidence” that can help “exclude or minimize potential alternative explanations” and provide “enough information to explain divergent aspects of the phenomenon” (Plano Clark and Ivankova, 2016, p. 9). Often in education, mixed methods are used to explore complex situations that involve multiple and often hierarchical interacting systems that are brimming with institutional uncertainties tied to *wicked problems* (Levin et al., 2012; Rittel and Webber, 1973). For example, research has shown that school attendance plays a vital role in a child’s educational outcomes. Attendance is often studied quantitatively to identify the number of absences for individual students. This information alone does little to improve attendance. Other approaches that include integrating quantitative and qualitative data are needed for solutions to be found. On this issue, Childs and Lofton (2021) advised that

Individually, the root causes of chronic absenteeism are not only in-school and out-of-school factors that contribute to chronic absenteeism, but also aid in the framing of chronic absenteeism as a wicked problem ... As a multifaceted problem, with causes and implications across multiple facets of society, chronic absenteeism should be tackled like other wicked problems ... (p. 214).

As shown, this type of multi-layered multifaceted *wicked problem* is ripe for a mixed-methods research approach. Table 1 shows additional examples of wicked educational problems explored using MMR approaches. The issues shown would be difficult to understand using solely a mono-method approach. For more information, see Onwuegbuzie and Mallette’s chapter on using mixed methods in educational research and Poth and Bullock’s chapter on designing complex mixed methods in this volume.

As mixed methods researchers in the field of education, we need to disseminate our research in ways that readers can fully understand and act. In her final remarks as editor for the Journal of Mixed Methods Research (JMMR), Mertens (2015) admonished that “business as usual will not lead to effective use of research to address wicked problems” and called for researchers to accept the challenge by “using mixed methods to respond” (p. 5). Craddock Lee (2021) shared that “mixed-method results can help bridge the gap for decision makers” improving research-to-practice (p. 99).

Table 1 Research studies using MMR to understand wicked educational problems.

<i>Author and year</i>	<i>Wicked problem</i>	<i>MMR approach</i>

Hunt-Anderson (2020)	Covert bullying	Transformative
Rouse et al. (2020)	Pregnancy and parenting teens	Concurrent
Theunissen et al. (2012)	Early dropout risk	Sequential explanatory

The purpose of this chapter is to build on the knowledge shared in previous chapters and to share best methods for reporting MMR. We will consider the guidelines from the [American Psychological Association Publication Manual \(2019\)](#) for which many journals and social science programs require, along with recommendations of the best practices highlighted in the seminal and current literature focusing on the critical aspects of reporting for the field of education. This chapter will assist the reader in the complex task of reporting quantitative, qualitative, and mixed methods strands within a single manuscript as well as offer recommendations for generating separate papers for each. We take a pragmatic step-by-step approach that encourages educational researchers to base their reporting choices on the relatedness of the methods and methodologies used, ensuring contextual relevance, and grounded in relevant theory. We include sections to provide guidance for framing your paper; selecting the title, abstract, and keywords; determining voice; writing each section from the introduction to the conclusions broken down into quantitative, qualitative, and mixed methods integration; and how to split into multiple papers. While we are limited to one chapter, we refer you to chapters offering more details on specific topics in this book and in other publications.

Deep consideration must be given to what ensures quality for mixed methods reporting. The standard of introduction, methods, results, and discussion grew from the development of reporting guidelines ([Altman, 2015](#)) but does not address the complexities of integrating quantitative and qualitative approaches. [Levitt et al. \(2018\)](#) found that “the thoughtful and robust use of mixed methods requires meeting the standards of both quantitative and qualitative research methodology in the design, implementation, and reporting stages” (p. 26). An example of the many typologies and designs supported for MMR is shown in [Table 2](#). Due to the number of possible purposes for using mixed methods, it is not possible in this space to address each one individually. In this chapter we share a basic approach to writing up an MMR study. Generating persuasive rationales, processes, and outcomes that use high quality criteria for mixed methods reporting is key ([Fàbregues and Molina-Azorín, 2017](#); [Poth, 2018](#)). [Wharton’s \(2017\)](#) study showed the most difficult part of research is dissemination. [Leech et al. \(2011\)](#) suggested having a framework to guide the writing process would “help to increase the rigor of mixed methods studies” and publications (p. 11). For more information on frameworks, see Plano Clark, Ivankova, & Yang’s chapter in this volume. Several others have suggested criteria for reporting mixed methods from the seminal typology of [Onwuegbuzie and Collins \(2007\)](#), the framework of Good Reporting of a Mixed Methods Study (GRAMMS, [O’Cathain et al., 2008](#)), recent guidelines for publishing in the JMMR ([Fetters and Freshwater, 2015](#)), the Mixed Methods Appraisal Tool (MMAT; [Hong et al., 2018](#)), and the American Psychological Association Journal Article Reporting Standards for MMR ([Levitt et al., 2018](#)). In addition, [Plano Clark and Ivankova \(2016\)](#) developed a socio-ecological framework to address the complexity and intertwining of domains to guide the entire research process including dissemination. Whichever you choose MMR reporting “must be defensible and transparent” ([Poth, 2018](#), p. 239). A well-written report will be one that another researcher can gather enough detail to reproduce the design, analysis, mixing, and reporting of the integration for each phase ([Reischer and Cowan, 2020](#)).

The context of mixed methods reporting

MMR uses the process of integrating quantitative and qualitative research to address a study’s purpose or research questions more completely ([Plano Clark and Ivankova, 2016](#)). To be considered MMR, a study must include (a) at least one quantitative and one qualitative method that are combined, which are (b) used rigorously and in accordance with the accepted criteria of the methodology and method used, where (c) the combination of the methods is carried out at minimum through a mixed methods design, and (d) the quantitative and qualitative methods are integrated in the study ([Creswell and Plano Clark, 2018](#)). [Hong et al. \(2018\)](#) caution that some research being reported should not be considered MMR including (a) those using a quantitative method that includes the collection and analysis of qualitative data but does not refer to the qualitative approach or method, (b) research using a qualitative method that includes the collection and analysis of quantitative data but does not refer to the quantitative approach or method, (c) a combination of multiple quantitative approaches only, (d) a combination of qualitative approaches only, (e) or the juxtaposition of qualitative and quantitative approaches without the integration of the two. Examples might include a quantitative survey with open-ended questions ([Creamer, 2018](#)), a qualitative interview that collects quantitative demographic data, or two

Table 2 Common examples of mixed method typologies and designs.

<i>Typology</i>	<i>Explanation</i>
Convergent parallel ^a	Quan and qual performed separate; brought together at interpretation
Explanatory sequential ^a	Quan first then qual used to explain quan results
Exploratory sequential ^a	Qual first then quan used to test or generalize
Embedded ^a	A strand of other type is added to enhance the overall design
Transformative ^a	Critical theory, shapes interaction, priority, timing, and mixing
Multiphase ^a	More than two phases
Parallel mixed ^b	One has two or more parallel quantitative and qualitative strands
Sequential mixed ^b	Strands occur across chronological phases
Conversion mixed ^b	Mixing occurs when one type of data is transformed to the other type and then analyzed
Multilevel mixed ^b	Mixing occurs across multiple levels of analysis
Fully integrated mixed ^b	Mixing occurs in an interactive manner at all stages of the study
QUAL + QUAN ^c	Equal-status concurrent design
QUAL + quan ^c	Qualitatively driven concurrent design
QUAN + qual ^c	Quantitatively driven concurrent design
QUAL → QUAN ^c	Equal-status sequential design
QUAN → QUAL ^c	Equal-status sequential design
QUAL → quan ^c	Qualitatively driven sequential design
Qual → QUAN ^c	Quantitatively driven sequential design
QUAN → qual ^c	Quantitatively driven sequential design
Quan → QUAL ^c	Qualitatively driven sequential design

separate studies conducted by the same researchers that were never intended to be integrated. Despite decades of setting mixed methods standards, these wrongly labeled studies can still be found in the literature and professional conferences.

A step-by-step approach to reporting mixed methods research

Framing your paper

When framing your paper consider that “the credibility of a mixed methods study rests almost wholly on the way it is reported” (Creamer, 2018, p. 280). Levitt (2020) advised that you need to clearly show the reader “from the start that both qualitative and quantitative methods are in use” (p. 112). Moreover, the use of mixed methods should appear in each section of your paper from the abstract to the implications. Further, the points of integration need to be explained to identify where the two are mixed or connected in some way (Schoonenboom and Johnson, 2017). Thus, you should provide a clear description the goals for the study’s quantitative approach, qualitative approach, and why there is a need for integration. Most of the standards and frameworks related to reporting MMR (e.g., APA-JARS Mixed, GRAMMS, MMAT, etc.) suggest whether strands are written about separately or interwoven, there should be continuity throughout the report. The approach should give the reader confidence in the integrity of your study and ability to replicate your research. Johnson and Christensen (2019) share that you need sufficient quality to achieve *multiple validation legitimation*, in other words meeting the relevant individual and combined quantitative, qualitative, and mixed methods validity needed. For more information, see Delmas and Giles’ chapter on qualitative approaches and Drisko’s chapter on quality reporting for qualitative research in this volume.

It may benefit the writer and ultimately the reader to capture your approach in a figure to visualize the order in which you will write (Plano Clark and Ivankova, 2016). Consistency throughout your writing is the key to translating your research to the reader. Typically, the order will be based on the sequence of use in sequential designs or in integrated or complex designs the importance of the approach or the purpose for mixing methods (Creswell and Creswell, 2018). Importance is usually determined by dominance, priority, weighting, emphasis, or status (Walker and Baxter, 2019). For instance, if one were conducting a mixed methods sequential exploratory designed study (Creswell and Plano Clark, 2018) where interviews inform the creation of a survey which is then implemented, the report would begin with the qualitative descriptions in each of the sections. If a study is run concurrently, but the

importance is on the quantitative findings, then the quantitative descriptions would lead each section of the report. Unpacking this, your study may use one of the commonly used designs shown in [Table 2](#) (i.e., [Creswell and Plano Clark, 2018](#); [Johnson and Christensen, 2019](#); [Tashakkori and Teddlie, 2009](#)).

For simplicity's sake, we leave it to the reader to determine the order of presenting their study. For the rest of this chapter, we will share how your chosen approach can be communicated consistently in each section of your paper.

Titling your paper

Imagine yourself in a brick-and-mortar bookstore or library. Slowly you walk down the aisles hunting the next book you will read. You pull out a few books, take a look at the covers, maybe you open to the table of contents or skim the first chapter. One appeals to you, so you drop it into your basket and continue your walk down the aisle. How did you choose what to read? What was the reason you decided to pull the book off the shelf? Usually, there is something about the title that appeals to you. You probably looked at the cover and either decided to buy it or put it back on the shelf. In most cases though, it was the title that first piqued your interest.

A title is often the most underappreciated component of the research reporting process. However, titles are the initial part of a written document that captures a potential reader's attention, whereby the reader determines whether a text is worth reading ([Zhi-jun and Jinfen, 2019](#); [Hallock and Bennett, 2021](#)). To prevent a paper from being dismissed, an article must have a proper title ([Soler, 2007](#)). A recent study showed that titles are a crucial decision-making element of grant applications, journal articles, reports, and documents, but they are often overlooked and almost never taught in the academic setting ([Anderson and August, 2020](#)). Titles assist readers to know the subject, methodology, and sometimes the context of your research. Often journals will have a word or character count for the title with a 15–20-word average. Titles should “indicate the topic and scope of the study,” and “be self-explanatory to readers” ([Swales and Leeder, 2012](#), p. 379) in “the fewest possible words” ([Day, 1989](#), p. 15). When crafting your title, you should include the methodology or design in the title. For example, “Urban high schools addressing the dropout crisis: A sequential explanatory mixed methods study.” This simple, 12-word title illuminates the topic and design indicating that the quantitative data shows school dropout rates are high, that the study focused on urban schools, and qualitative data was collected to explain the phenomenon. The title may not illuminate the complexity of the research, or the number of methods used, but it does give the reader a basic understanding of what to expect. It is also necessary to include an author's note on the title page acknowledging any funding sources, contributors, conflicts of interest, or special circumstances.

Abstract

The abstract is your reader's first glimpse of your study, and you should keep them in mind at the forefront of your writing ([Creswell and Plano Clark, 2018](#); [Leech and Onwuegbuzie, 2011](#)). A helpful metaphor put forth by [Leech \(2012\)](#) is to think about drafting your report as you would a cooking recipe with all the necessary ingredients and the process of the actions taken by the researcher, clearly delineated. This applies to the abstract as well. In your abstract, you should succinctly (a) state the problem, questions, and hypothesis or phenomenon of the study, (b) describe the participants and other data with pertinent characteristics, (c) indicate the mixed methods design, including how intersecting approaches to inquiry are combined, (d) the analytic approach, (e) the main findings, and (f) implications and significance. When the viewer finishes reading your abstract, they should be able to have a basic understanding of your study.
